PHILOSOPHICAL INVESTIGATIONS

IN

GREAT BRITAIN.

PERMIT me, Gentlemen, to lay before you this fmall Publication, containing fome ingenious obfervations lately communicated to the public in the German language by Mr V. Uflar. I embrace this opportunity to make known to you a Gentleman, whofe laudable endeavours are directed to the improvement of that part of the knowledge of plants and of vegetation, which has hitherto appeared the most obscure, and which has yielded least to the investigations of philosophy.

I have no doubt, but that fome of you, to whom the various fciences are already fo much indebted, will deem it not unworthy of them to examine the contents, and to improve upon what is here delivered. I have purpofely avoided making any effential alteration in Mr V. Uflar's obfervations, and I have omitted no part which appeared interefting refpecting the object of his publication, or which I knew to be not generally known in this country. But I have prefixed a general view of those principles, and of fuch of their properties, as I thought most worthy of attention, in the proper investigation of that interesting fubject. As I confidered part of the obfervations related in the original work, as not yet fufficiently and accurately afcertained, and that much must still be done towards the complete establishment. of

(vi)

of the theory, I have taken the liberty of inferting a fhort sketch of my ideas refpecting Light and its properties; in expectation, that this may be honoured with examination, by those who wish to contribute towards the improvement or correction of the fubject of this publication; a fubject, furely well deferving the attention of experimental philosophers. Whatever I have to fay upon, or to add to Mr Uflar's communications, I have purpofely postponed; as I have many experiments in view, which I shall perform with all poffible accuracy, and of which, I fhall communicate the refults at another opportunity.

I hope to give then alfo an account of fome fubequent obfervations, which Mr V. Uflar has promifed on this fubject; and to be able to prefent fome new obfervations, made by the ingenious Mr Hedwig, Hedwig, whofe merits are already well known to many in this country; and probably alfo, to make known fome new difcoveries, which I anxioufly expect from Mr V. Humbold, a Gentleman already celebrated among the learned in Germany, by fome ingenious publications on this fubject.

> I have the honour to be, Gentlemen, Your most obedient fervant, G. SCHMEISSER.

INTRODUCTION.

HAPPILY the time is arrived, when Chemifts and Phyfiologifts unite their endeavours to inveftigate the nature, conftruction, composition, and functions of the vegetable tribe; in order to perfectionate our knowledge of the Economy of Plants, and to difplay the many interesting and entertaining particulars, which the fludy of this branch of science is calculated to afford.

Many arts and fciences have already derived great advantages from the aid of chemiftry, by the many improvements which that important fludy has fuggefted. But though Botany has met with great admirers, and has been cultivated by many original geniufes, little has it been advanced in proportion, by chemical chemical and phyfiological inquiries into the nature of vegetables.

Chemifts by their ufual ardour of invefligating every body which prefents itfelf to them, have indeed difcovered and pointed out, the immediate component parts of vegetables, and their various products or combinations. By afcertaining many of their chemical properties, they have flown how they may be further prepared to ferve for alimentary, medicinal, and other ufeful purpofes in the arts and manufactures.

What variety of fucceffive phenomena do we perceive in vifiting our gardens, fields, forefts, and meadows, from early fpring, till the clofe of the autumn; when, during this petiod, plants make firft their appearance, proceed in their growth, and attain to perfection. But we fhould not be fatisfied with admiring their external beauties, with knowing how to diftinguifh them by their external characters, and with collecting them or their products whenever

(x)

whenever they are fit to ferve for our various purposes. Nor are we entitled to enjoy the contemplation of all the phenomena, and receive the manifold donations of those products of nature, nor furely to murmur at their accidental failure, or untimely decay, without enquiring more particularly into the caufes of their diseases, to remove them if poffible; and endeavouring to inveffigate the origin and progrefs of all these phenomena, and the causes whence they refult : e. g. To afcertain the food of Plants, and the fituation best fuited to their respective constitutions, and the means by which they may most certainly obtain their proper nourishment; to difcover their natural affociates, as well as those which are inimical to them. Laudable, must therefore be every attempt or endeavour, which tends towards difcoveries or improvements on fo interesting a fubject.

It is the express defign of the present treatife,

(xii)

tife, to enquire into feveral of these interesting particulars. How far the Author has fucceeded in his endeavours, the candid reader must judge.

ON

V Ě Ġ Ė T A T I O N.

I N attempting to inveftigate the economy of vegetables, it is neceffary to have a general knowledge of those substances and principles, that are found to furnish and produce the requisite supplies for the purposes of vegetation, as well as of such as may tend to deftroy these supplies. Later discoveries in chemistry have shown that these principles are chiefly the following:-Matter of HEAT:-Matter of LIGHT: -OXYGEN:-HYDROGEN:-AZOTE or NITRO-GEN:-CARBO:-and their combinations.

A

HEAT.

HEAT.

THIS elementary principle, exifting in all bodies, manifefts itfelf by numerous phenomena refulting from its effects. It exifts in different ftates according to circumftances afterwards to be mentioned.

In one, (probably its original ftate,) it is not perceptible by our organs of fenfation, and is apparently inactive upon other bodies exifting within its atmosphere. This ftate of heat, properly defined Latent Heat, is the fource of all its other ftates, in which it becomes fo powerful an agent for innumerable purposes necessary for organized bodies. Immortal, therefore, be the name of that great philosopher, DR. BLACK, to whom we are indebted for its complete discovery, which has led to fo many subsequent useful discoveries in chemistry.

Latent

Latent heat, we find, exifts in different proportions in different bodies; and bodies have a different capacity of imbibing, accumulating, and combining with it.

The other flate of heat, is that in which it manifefts itfelf to our organs of fensation; and in which it becomes active upon bodies prefented to it. This state is occasioned by different causes. For inftance, latent heat is fet at liberty, fo as to become active, by certain exchanges of the condition, or component parts of bodies, refulting from fuperior elective attraction among heterogeneous bodies, when brought into near contact; as we obferve, by the feparation and exchange of the bafis of oxygen gas, in the process of combustion and refpiration ;-- by the conversion of vapours into liquids, and of liquids into folids ;-- by the crystallisation and sudden concretion of faline, vegetable, and animal fluids ;--by the fudden abforption and condenfation of fixed air and water by earths. &.c.

Whenever heat, in any of the above-mention-

A 2

ed

4

ed cafes, is fet at liberty from a body, it always difcovers a tendency to enter and pervade another prefented to it, owing to its general attraction for all bodies; on which account it cannot be confined, nor exift, in a perfectly free, or uncombined ftate.

The different degrees in which heat becomes more or lefs perceptible and active when fet at liberty, will be in proportion; first, to the quantity of latent heat in bodies; fecondly, to the quantity which is feparated in a given time from bodies acting upon one another. Its effect on the fubftances to which it is applied, will be according to the velocity with which it can enter that body, and also in proportion to the capacity of the ambient, or intervening medium, for accumulating or retaining it. If, for inftance, a homogeneous body, or alfoa chemical compound, be exposed to fuch a degree of heat as is incapable to deftroy the chemical attraction of the parts of the compound, it then will gradually produce an equal effect upon fuch aggregate; namely, it will merely

2

enter,

enter, occupy, and be accumulated in the most minute interflices of that body, and thus exert its expansive force, or felf-repelling power, and thereby increase the bulk of the body, diminish its fpecific gravity, and occasion an alteration in it, which will continue only as long as heat is fupplied; and the expansion will be in proportion as the quantity of heat supplied can overcome more or lefs the power of attraction of cohefion of particles, under the preffure of the atmosphere. In this cafe, on removing the body from the fupply of fenfible heat, its parts will refume their former flate without having undergone an alteration in their nature; confequently, the heat applied to fuch had only produced a temporary effect. Examples of this we observe in the conversion of ice into water,-of water or spirits of wine, or effential oils, into vapour,-in the melting of wax, fat, gelatinous matter, metals, &c.

There are other cafes, in which fenfible heat when induced in a moderate degree, upon bodies of a heterogeneous mixture, will first occafion

fion a fimilar effect; yet fuch bodies will be more or lefs decomposed or destroyed by an intense heat.

Inftances of the effect of a moderate degree of heat occafioning a mere feparation of the conftituent parts of a mixture, without the production of a new compound, we can obferve, on applying a moderate heat to a mixture, of fixed falt and water, of spirits of wine and water, of water and earthy matter, ----to animal and vegetable fluids,--oils, and other vegetable matter, &c. In this cafe, the applied heat first pervades and expands the mixture, and then accumulating, gradually exerts a different effect upon each of the bodies, which effect will be in proportion as their capacity of retaining heat is to the power of attraction and cohefion between the particles of each of the bodies in the mixture. If, therefore, the capacity of one of the bodies (as water), for accumulating heat, exceeds the power of attraction of cohefion among its particles, and if the power of attraction of cohefion among

mong the particles in the other body (as falt), exceeds its own power of accumulating heat, then the expansive force of heat upon the particles of water, will be greater than that upon the particles of the falt, and as thus the specific gravity of water is diminished, the latter will confequently separate first, and will remain sufficient of the atmosphere until it part again with that heat. When this happens, the water recovers its former state, and the falt remains undecompofed, parting likewise gradually with its share of accumulated heat and then the applied heat will be set at liberty again.

Another effect of fenfible heat applied in a great degree to bodies of a heterogeneous nature, is a more permanent alteration or a total exchange of the component parts. Here a certain portion of fenfible heat combines chemically or more intimately with fome of these parts, and becomes thus latent, producing a new permanent and elastic compound (or gas), in which the heat remains in combination in the temperature

rature of the atmosphere in which it then exifts. and can from that flate be feparated only by expoling it to fuch a body, as has a fuperior elective attraction for the fubftance to which it is combined. For inftance, if we expose animal or vegetable juices, inclosed in a veffel, to a moderate heat, we observe, that the aqueous or more volatile parts first separate, and the less volatile remain; but when more heat is applied, then an exchange, or new combination of the component parts of the refiduum will take place, and part of the applied heat will enter into a chemical or more permanent union with fome of the principles of the compound, and produce thereby hydrogen gas; or it will combine with a new compound, as carbonic acid, and form the fixed air. Thus we perceive, that no specific effect can be appropriated to fenfible heat, fince much depends on its quantity and on the disposition of bodies, either to accumulate merely or to combine it.

Senfible heat in a moderate degree applied, promotes vegetation in a variety of ways; it excites the activity of plants; it promotes the difpofition polition of some of their conflituent parts for new attraction and combination, to obtain such subfrances as may be requisite for their growth; it likewife causes them to reject such matters as would be hurtful to them in retarding their growth, &c.; it promotes the diffolution or digestion, the formation, and secretion of their different products.

It fupports the irritability of fome of their parts, in difpofing them to acquire and to retain a due proportion of the principle (the oxygen hereafter to be explained) which caufes their irritability; and in preventing alfo the accumulation of this principle in plants, which may become hurtful to them.

It renders their food and juices, &c. more fit for penetrating and paffing their different conducting canals; and enables them to difpofe of their fuperabundant portion of fluids, by promoting perfpiration and evaporation.

It is also active in the production of electrici. ty, which likewise affists vegetation.

B

Senfible

Senfible heat becomes alfo ufeful to vegetation in another way: after plants or animals have finished their period of life, or when purposely deprived of it, heat then occasions a diffolution, and new combination of their component parts, by fermentation, &c. according to the nature of the vegetable or animal matter; and thereby promotes the preparation of new food for living plants.

Thus we observe the numerous beneficial effects which heat has upon the process of vegetation.

But heat may prove fatal to the confliction of plants when applied in too great a degree, and for too long a time; as this may occafion a too rapid digeftion and perfpiration of their nourifhment, and confequently an exhauftion. In fuch cafes, plants will only recover by diminifhing gradually the application of fenfible heat, either by occafioning a flow evaporation of water upon their parts, or by other means.

LIGHT.

ON LIGHT.

21

LIGHT.

LIGHT I confider as a matter exifting in bodies, and which, like matter of heat, may exift in different proportions in different bodies. It can manifest itself in various states, according to the capacity of bodies, for attracting, detaining, or combining with it, whenever it is fet at liberty from one body, and induced upon another.

Light, in many of its properties, appears to differ from matter of heat; but heat feems to be a neceffary agent for its perceptible and active ftate. I am alfo of opinion, that the production of the fenfible ftates of both light and heat, refults from their mutual action upon each other when excited.

Light does not enter into the composition of all bodies. Such as do not contain it, are not fit for inflammation, as earths, &c. but fuch bodies may

may imbibe a fmall portion of light; but they can retain it only under certain circumftances connected with the nature of their composition and ftructure, and according to the degree of external preffure acting upon them.

Bodies which contain light in their compofition, and which are neceffary for inflammation, or/for the production of perceptible and active light and heat, and which in the combination with oxygen produce no permanent gas, I fhall call *perfect inflammable* bodies, fuch as fulphur, phofphorus, hydrogen. And fuch bodies as contain it only in fome of their component parts, and which produce gas during their inflammation, I fhall call *femi-inflammable* bodies; as oils, camphor, fpirit of wine, wood, &cc. And we may thence fuppofe, that bodies contain more or lefs light in their compofition, in proportion as they exhibit the phenomena of inflammation, when properly difpofed for it.

Light and heat may, at the fame inftant, be feparated

feparated from certain bodies (though not ftrictly inflammable).

1/t, By external caules, as by collifion, friction, or condensation. The production of sparks, when two bodies, as flint and steel, &c. are suddenly and violently struck together, affords a familiar example of this separation.

2dly, Light may be difengaged from its combined flate, by the mutual action and new combination of certain heterogeneous bodies. To occasion this, it is not only necessary that at least one of the bodies be an inflammable one. and that those bodies which are to act upon one another have a chemical attraction for combination, and be affifted by fenfible heat neceffary to promote their attraction; but alfo, that the one body have an attraction for the bafis of the inflammable body, fuperior to that which the basis has for light.----Farther, two heterogeneous bodies, whatever they may be, which have no chemical attraction for one another, cannot combine, and confequently cannot

not emit fenfible light and heat. Hence we obferve no fuch interchange takes place on mixing fulphur or phofphorus, with gold, platina, &c.; or hydrogen with fulphur, or phofphorus, exposed to fenfible heat. An intimate combination of fuch a nature, therefore, of two bodies, as mentioned before, is neceffary for the production of inflammation.

Senfible light thrown upon bodies which do not tranfmit nor reflect it, but which imbibe it, but do not retain it, feems to difengage their latent heat; and combining with the latter, gives to it elafticity, and thus produces by fuch combination fenfible heat.

We likewife obferve, that inflammable bodies cannot produce the phenomena of inflammation, or emit fenfible light without the affiftance of fenfible heat; and many inflammable bodies will not part with their latent heat, unlefs their latent heat is excited by fenfible light. In the inflammation of an inflamed body, a mutual action

ON LIGHT.

tion and re-action of both principles appears to take place: and accordingly it feems that camphor, refin, fpirit of wine, oils, &c. will not inflame by the mere application of heat: but they will do fo if fenfible light, accompanied at the fame time with fenfible heat, is applied; as, for inftance, in the cafe when the inflammable body is excited by flame.

It likewife appears, that heat alone cannot difpofe all inflammable bodies to combine with the oxygen from the atmosphere; the matter of light latent in these bodies having perhaps a greater attraction for either of their combined parts; and that they will therefore not give out their light until their latent heat be at the fame time excited by the action of fensible light applied.

When light is fet at liberty during this combination, it will then be visible or not, according as it is, or is not, disposed to combine with another matter, in the moment of its being fet at liberty. For instance, when light fet

at

at liberty, is immediately, either partly or wholly, difpofed to unite with another matter, as that of heat, to produce claftic fenfible heat; or when that again is employed for the production of gaffes or vapours, then little or no light will become perceptible, and more fenfible heat will refult accordingly from it. But when light is fet at liberty in a greater proportion from the inflammable body, than what the matter of heat in thofe 'excited bodies can confume, or combine with, for the production of fenfible heat, and where no elaftic fluids are produced which can take it into their composition; then more light will become perceptible, and in proportion active.

The perceptibility, or active power of the light extricated, will be greater in proportion as the excited bodies yield that principle in a greater quantity, and as the velocity with which it can enter the bodies is greater, and as bodies can combine more readily with it. The more flowly the combination of fuch bodies takes place, the lefs

lefs will be the quantity of light feparated at the time, and confequently, the lefs its effects.

As the difpofition of bodies for chemical combination is promoted by heat, it therefore feems that heat is a neceffary medium for inflammation; and that, therefore, much depends upon the degree in which that agent is applied to bodies difpofed for combination. We obferve but a fmall quantity of visible light by exposing phosphorus or fulphur in the atmosphere of a low temperature, and a great portion, when more heat is applied.

We fhall now endeavour to explain, how oxygen gas is not always neceffary for the production of light and heat. The combination of other bodies may occafion the fame phenomena, provided that one of the bodies be an inflammable one, and confequently containing light, and that all the other circumftances formerly defcribed be prefent. For inftance, if we difpofe fulphur and certain metals, as iron or copper, for combination effected by heat, we perceive the **C** fame

fame phenomena, namely, the production of light and heat, without their being exposed in oxygen gas, or any other gas containing that principle; which experiment was lately performed by fome well known Dutch chemists, and which any one may eafily repeat: indeed the above-mentioned fubstances will exhibit the phenomena in azotic or hydrogen gas, or in a vacuum; but inflammable bodies, exposed in either of those gasses *per fe*, cannot do this, because they do not under these circumstances enter into combination with the basis of either of the gasses, which would be necessary, as observed before.

Oxygen can only produce these phenomena, when it is exposed to inflammable bodies for which it has an attraction of combination, such as sulphur, phosporus. And it produces the phenomena in a greater degree than other substances, from its superior and more rapid attraction for, and combination with those bodies; and likewise, from the circumstance, that the combinations of these bodies dies are not attended with the production of gaffes and vapours. It may now be perceived, how oxygen is a neceffary medium for the production of light from fuch inflammable bodies as are chiefly composed of hydrogen, as spirits of wine and oils.

Oxygen is likewife requifite for the production of fenfible heat in the combustion of charcoal, as it has a strong attraction for that substrance. From these and other observations we conclude, that more fensible light and heat are produced by inflammation, in proportion as that process is less attended with the production of elastic fluids.

If, therefore, the proportion of hydrogen exceeds that of carbo in femi-inflammable bodies, then there will be more light fet at liberty; and on the other hand, if the carbo predominates, there will be lefs light and more heat.

Now, in the inflammation of fpirits of wine, oils, &c. in oxygen gas, there are both light and

and fenfible heat fet at liberty, which continue perceptible, as long as the fupply of both continues. But, we perceive, that this procefs is attended with a continual lofs of light and heat; which is to be accounted for, as a certain quantity of light is immediately employed in the production of fenfible heat, from the inflaming body; that a great quantity of heat is likewife employed in the production of fixable air, arifing from the combination of carbo in the femi-inflammable body, and the oxygen from the atmosphere; and alfo, that another portion of fenfible heat is employed for the formation of vapours from the water which is formed by the combination of oxygen from the atmosphere, and the hydrogen in the fpirit of wine : Whereas, by the combination of phosphorus or fulphur, there is no heat combined, and there is no gas and no vapour produced, as explained before; and that portion only of light difappears,

pears, which was neceffary to excite the latent heat in those bodies.

Light, when thrown upon bodies, which do not transmit nor reflect it, but which have a capacity of imbibing it, may become active upon fuch bodies, as is the cafe in plants, either by combining ftrongly with their latent heat, and converting that into fenfible heat; or by occafioning, at the fame time, a feparation of the oxygen or other matter of fuch bodies, with which it can combine; and thus, in conjunction with matter of heat, produce elastic fluids: or it may partly be detained in bodies; and fuch bodies will emit it gradually again in the ftate of visible light; as we observe of certain fubstances. This property of accumulation and emiffion of light by certain bodies, is more perceptibly occafioned in them, when previoufly prepared for it by the effect of heat; first in producing by heat an expansion of fuch bodies; then exposing them to a ftrong light, as that of the fun; fuch bodies will, in proportion as they

they poffels thole mentioned qualities, imbibe more or lefs of that light, and will give it out again in a vifible flate, in proportion as they contract, and when placed in a dark room. This we obferve in a certain fpecies of heavy fpar, called Bononian flone, and other fubftances. There are falts which, when expofed to much light during their cryftallifation, will afterwards emit light; other falts will emit light when rubbed in a mortar in a dark place; as, for inftance, the corrofive fublimate, &c.

Light thrown upon bodies, which do not transmit nor combine, but which reflect it, produces no sensible heat upon them, and it suffers no change. This we observe when sensible light is thrown upon certain metals with a polished surface.

Senfible light, falling upon bodies which are transparent, as glass, gasses, &c. when perfectly homogeneous, is transmitted, and has no apparent effect upon them. Thus the more homogeneous that such bodies are, the less is the diminution.

nution of the intenfity of the light which pervades them, and the lefs is the fenfible heat which is produced in them. This coincides with M. De Luc's opinion, that there is in proportion more light induced upon bodies, exifting on or near the fummits of high mountains, and confequently lefs heat produced in that atmofphere ; and that there is lefs light reaching the furface of lower ground, as the light defcending through the lower region of the atmofphere to the earth, is partly abforbed, and varioufly interrupted by the heterogeneous bodies in the lower atmofphere, by which the intenfity is greatly diminifhed.

From what has been obferved refpecting the properties of light, we may perceive in what refpect light may be beneficial to plants in general.— Light induced upon plants, may excite heat, occafion the feparation of oxygen, and convert other matters into elaftic fluids. It may greatly contribute to the formation of the inflammable matter produced in plants, fuch as oils

oils and refinous matters. The formation of fuch fubftances is very remarkable in hot climates, and perhaps chiefly depends on the faculty poffeffed by light of feparating the accumulating oxygen, as oxygen deftroys the inflammability of bodies.

Light, therefore, feems thus to promote the increase of inflammable matter, only in those plants whose component parts have not a greater attraction for oxygen, than the oxygen has for light and heat, as we may expect in plants which affume an acid nature.

^b Light induced upon plants occafions a change in their colour, either by entering into their conflitution, or by feparating the oxygen which caufes, in proportion to its quantity, a modification of their natural colours; and by which feparation of oxygen, it fupports the irritability of plants, as that appears to depend upon this principle, as has been before obferved.

Living plants difcover a difpofition to attract light, and when in want of it, fearch for it, and direct direA the extension of their tender or flexible parts towards a place where they can reach it. Certain parts of plants, as flowers, manifest a difposition to prefent themselves, fo as to receive fully the rays of the fun, or they direC their faces towards the fun: This disposition, Mr Girtanner as to the effect of light upon certain fibres peculiarly constructed, as will be seen in the sequel of this book.

I shall finish the subject of light with the observations, that plants may receive light from gasses which contain it, as before mentioned, by imbibing and decomposing them; and that plants, may thus receive light, when growing in a fituation excluded from the subject of light.

D

OXYGEN.

OXYGEN.

OF all the principles neceffary for the fupport of organized bodies, oxygen may be confidered as one of the moft active. It received that name, which fignifies the generator of acids, from its inveftigator MR. LAVOISIER; who found it to be a neceffary principle in the formation of acids. The exiftence, and fome of the properties of this principle, were already known to, and related by, Dr. John Mayow*; and alfo by Dr. Rutherford, the difcoverer of phlogifticated air. But Lavoifier has certainly inveftigated its properties, and active powers, more than any other chemift; and has confequently the greateft merit.

* In a Treatife published in 1674.---Oxford.

merit. It exifts in different bodies, varioufly combined, and manifefts itfelf, by the various effects which it produces when feparated from any of its combinations, and when acting upon other bodies, and entering into a new combination with them.

It is fet at liberty from its combined flate in confequence of other bodies acting upon it, or upon the fubstances with which it was combined, by a fuperior power of chemical elective attraction. 1/t, It exists in water, combined with hydrogen. 2dly, In the atmosphere, combined with matter of heat, (and as I believe, likewife with light) and conflitutes, in that ftate a part of the atmosphere, to which it. gives the quality of fupporting life, combuftion, and inflammation, 3dly, It exifts in fixed air, combined with carbonaceous matter, to which it has a ftrong attraction. 4thly, It is the principal component part of acids, combined with the acidifiable fubstance of animal or vegetable matter. 5thly, It, exifts

ifts combined with metals, which it deprives of their luftre, inflammability, cohefion, &c; and, which are thereby rendered capable of entering into different combinations with other bodies. It has, when applied to vegetables, a great effect upon their growth; and, when plants are too much deprived of it, or when they are overloaded with it, it then proves hurtful to their conflitution. It contributes to the motion of plants, as it caufes the irritability of fome of their parts; and the various degrees of this irritability depend on the different proportions in which it enters, or is accumulated in them. The due proportion, which plants thus require for their irritability. &c. depends, likewise, upon the substances which furround and act upon them. The fupply of this principle is produced by fuch fubftances as contain oxygen; and this, the more readily, according to the weaker combination of the oxygen with the other fubftances with which it is united : Hence, combinations in which which the oxygen is retained with very little force, as for inftance, fuper-oxygenated muriatic acid, are most fit for that purpose; for plants can only obtain the oxygen from its other combinations, in fo far as they have a power of occasioning a decomposition of these combinations. But this power depends much on the temperature in which the plants grow.

Whenever plants imbibe oxygen, in a greater proportion than what they naturally require; (which may be occafioned by the abfence or diminution of the principle which caufes the feparation of oxygen), then an accumulation of oxygen takes place, which occafions a proportionally greater degree of irritability; and which, confequently, may become hurtful to the conflitution of plants.

The principles which caufe the feparation of the oxygen, are light,—hydrogen, affifted by heat. Hence, the due proportion of oxygen in plants, depends on the different degrees in which any of thefe principles are applied, or can

can act upon them. Thus, a moderate portion of thefe exciting principles will occafion a prefervation of the due quantity; a lefs degree, an accumulation; and a greater degree, a diminution: The two laft will occafion a gradual exhauftion of fuch plants.

Oxygen has alfo a great effect upon the colours, and upon various parts of plants; and greatly contributes to the formation of their products. It is an afcertained fact, that the fuper-oxygenated muriatic acid, which has been found to confift of 1,856 parts of muriatic acid; 98,105 of water; and 0,093 of oxygen, deprives green plants of their colour; or changes them into white, yellow or reddifh. What takes place by that acid immediately, can but flowly proceed by the oxygen in the atmofphere, owing to the almost equal attraction which oxygen has for the colouring matter of the plants, and for the matter of heat and light.

It appears, that the colours of plants become paler

paler the more oxygen they imbibe, and that the modifications of the green colour depend on the different proportions of oxygen. Thus, we may explain many phenomena that occur during the vegetation of plants. The hilum of young feeds is generally colourlefs, fo are the petals of the flowers, when perfectly included in the calyx.—Leaves, when they first appear, are of a pale colour; owing probably to the oxygen, which, at that period only, begins to be extricated by the effect of light and fenfible heat; and thus permits the colouring matter to make its appearance. In the fame manner, may the change of the green colour of leaves into yellow, which we observe in the autumn, be explained. Vegetation generally ftops in that feafon, and plants then approach. to their winter's reft; the fecretion of oxygen diminishes, and the quantity gradually accumulates during that time, and confequently deprives them of the green colour.

The extraction of oxygen from plants by the effect

effect of radiant light, arifes perhaps, from the fuperior attraction of oxygen for light. Some plants, as tremella,—noftoc,—filices,—mufci, and algæ, retain the oxygen weakly, and part with it eafily.

This explains how plants change their colours, by the free accefs of air; why plants growing in the fhade have generally a pale colour; and why plants, entirely excluded from light, lofe their colour; as in that cafe they are deprived of, or excluded from, those agents which occasion a fecretion of the accumulating oxygen, on which the change of colours chiefly depends *.

The feparation of oxygen from plants, may be afcertained, by applying a little diluted aacid, fuch as oxalic, nitric, &c. Plants, or their parts, which contain much oxygen, and part

* That hydrogen gas, applied to plants excluded from light, occasions a feparation of their accumulating oxygen; was first afcertained by Mr. Humbold.

part eafily with it, are generally green; and thofe which contain a great portion, but lofe it with more difficulty, are, in proportion, either white, or fpotted : As for example, Lichen *miniatus*,—L. *parietinus*,—L. *verrucofus*,——different petals,—ripe apples,—barks,—and bracteæ, when growing in the fhade.

The different effects which oxygen produces upon plants, when growing in different places, and exposed to a different atmosphere, have led feveral botanists to mistake trees of the fame species: For example, the betula and tinus, growing upon the *Brokken*, (a high mountain in Germany on the Harz) on account of their fmaller fize, and deeper colour of the leaves than usual, when growing in a different atmosphere, have been mistaken for new species. Such variations had been afcribed to the effect of different climates and soils; but botanists did not suspect, that any such effect arose from that great agent oxygen.

The

The caule of the deeper colour of those plants, or of their leaves, is probably,

a. The more intenfe light, tranfmitted through the atmosphere furrounding the fummit of fuch a mountain, and acting freely, on all fides, upon those folitary trees.

b. The different flate of the purity of that atmosphere, and the fuperior capacity of that fluid for receiving oxygen.

c. The ftronger, and more lafting cold, which caufes a great alteration in the irritability of plants by the increase of oxygen; which is, in proportion, separated again by each increasing degree of light.

The effect of light, oxygen, and carbo, upon colour, is equally obfervable in animals and plants. Befides the well known obfervations, that the products of hot climates are of a deeper colour than those of the northern; Mr. Uflar obferved, that he found repeatedly, the rana *arborea* change its colour, by living in different

ferent fituations; the more it was exposed to the fun, the deeper its green colour became; and the green colour changed into a whitifh grey, as he obferved alfo of fome plants, when it had lived a confiderable time mostly excluded from light, or when confined within walls. Perhaps, aliment, climate, and confinement, contribute to the change of colours in organized bodies.

The exiftence of oxygen in plants, is fhown by their becoming acidified, or oxydated; and by their undergoing an acid fermentation. Befides, it is found, that certain plants contain perfect acid in their composition. Such are generally of a pale green colour, as the oxalis *acetofella*. The boletus *fuberofus* yields faccharine acid during its growth. The oxygen gas which, we obferve, is extricated from plants when exposed to the effect of light, &c. affords another proof that they contain oxygen, or take it into their conflictution.

The colouring matter of plants appears to refide in, or to be produced in, the refinous parts, in

in combination with oxygen : For inflance, if we extract the green parts of plants by fpirits of wine in a veffel excluded from light, filter the infufion, and fill with it a phial half full, and expofe it flightly corked to the rays of the fun, or to the light of a large burning lamp; we then obferve, that the green colour foon inclines to yellowifh. This change, however, does not take place if the bottle is totally filled, or excluded from the accefs of pure air; nor when the infufion is kept in a phial, in contact with nitrogen or hydrogen gas. So we find, that the tincture of turnfol, when excluded from light, retains its colour, but lofes it on expofure to much light.

Oxygen renders many volatile fubftances more fixed in the fire; as we obferve of fulphur, phofphorus, and vegetable fubftances, when combined with it. It alfo deftroys the inflammability of bodies by its combination. Though it appears, that oxygen, when in great proportion, covers the colours of plants; yet it likewife feems,

feems, that in a fmall proportion, it contributes to the formation of certain colours. Thus, Dr. Bancroft, in his learned treatife on permanent colours, attributes the black colour of charcoal to the combination of oxygen with the carbonaceous matter; and he confiders the charcoal as an oxyd of carbon. He obferves, that the tincture of violets, when it has loft its colour in clofe veffels, recovers it by oxygen gas.

Oxygen feems also to be the principal cause of the different colours of the oxyds of metals.

We fhall conclude this article, with an extract, containing the refult of the ingenious obfervations made by Fourcroy; who proved the existence of oxygen in plants, by analytical and fynthetical experiments. He observes,

1. That oxygen combined with vegetables alters their colour:

> a. Their colour becomes paler by an increafe of oxygen,

b. Deeper by a diminution of it.

2.

2. The various modification of colours, exhibited by plants, depends on the different proportion of oxygen, which they take into their conflitution.

3. Plants faturated with oxygen lofe their green colour entirely; and a yellow colour is the refult of the change.

4. Plants not faturated with oxygen, may appear violet, blue, brown, or purple.

5. Oxygen entering into the conflictution of plants, occafions a change in their nature, in proportion as they imbibe it. Oxygen likewife appears to be favourable to the formation of refinous matter.

HYDROGEN.

HYDROGEN.

THIS principle we cannot, as yet, exhibit in a feparate flate, its properties are only difcoverable by its combinations. In its combined flate it manifefts remarkable phenomena, which differ according to the nature of the fubflance with which it is combined.

It exifts principally in the composition of water, which has been verified by fynthetical experiments, made by the ingenious philosopher MR. CAVENDISH, and Lavoisier; and it thence received its name, which fignifies the generator of water.

In the composition of water, it is combined with oxygen, and in this flate it is not immediately inflammable; but, when that combination is deflroyed, by the effect of a fuperior elective

lective attraction, of certain bodies, for the oxygen with which it has united; as for inftance, by metallic fubftances or charcoal; it then is fet at liberty, fo as to enter into another combination; in which cafe it affumes a different ftate, and exhibits different phenomena, according to the nature of the matter with which it combines.

If it unites merely with fenfible heat, it then produces a compound which is inflammable, or which, when light and heat is applied to it in contact with atmospheric air, is capable of exhibiting the phenomenon of inflammation; in that ftate it is called hydrogen gas or inflammable air.

This compound elaftic fluid is lighter than atmospheric air, or any other gas; it does not fupport life nor combustion like oxygen gas; but it is in that state, capable of difengaging the accumulated oxygen from plants as observed before. When it is set at liberty from the composition of water, without the prefence of a fufficient

ON HYDROGEN.

fufficient quantity of fenfible heat, it then has a difpofition to unite with other matters; as, for inftance, with carbonaceous matter, and may thus produce an oily compound, or enter into other compositions, and thus become an aliment to plants.

Sometimes we obferve, that plants emit hydrogen in the flate of inflammable air; fuch as; DICTAMNUS *albus*, or FRAXINELLA, when it is in flower; and likewife most of the fungi and byffi, by reason of the greater attraction of their component parts for oxygen.

Sometimes the hydrogen gas thus emitted by plants is obferved to have united with a little of carbonaceous matter; and in that cafe, the heavy inflammable air is produced; fuch is the air emitted by agaricus *campeftris*.

Occafionally we find plants containing fulphureous or phofphoric matter; and fuch plants may emit the hydrogen in the fate combined with either of thefe, and it will therefore appear in the fate of either hepatic air or phofphoric gas.

Æ

AZOTIC

AZOTIC PRINCIPLE.

THIS matter we cannot exhibit in a feparate ftate, its properties are only diffinguifhable in its various ftates of combination.

In the flate combined with heat, it was firft difcovered by the eminent Chemift, DR. RUTHERFORD, Profeffor of Botany at Edinburgh; it was then called Phlogifticated Air, but now Azotic Gas, on account of its having the oppofite quality to that principle which fupports life. It exifts in the flate combined with heat in the atmosphere; and mixed with a certain portion of oxygen gas, it forms the effential compofition of atmospheric air.

It exifts in the atmosphere, apparently for the purpose of modifying the effect of that powerful agent, the oxygen, in the process of respiration tion of animals and plants; as oxygen gas alone may become hurtful in many refpects. It ferves alfo for modifying the rapid effect of oxygen during combustion and other operations, and thus alfo enables us to modify the heat extricated from bodies during their decomposition and combination.

It is most likely, that in that state in which it exists in the atmosphere, it enters into combination with another body, and produces new compounds.

It conftitutes, according to the difcovery of Cavendifh, Lavoifier, and Prieftly, the bafis of nitre and nitrous acid, and alfo of nitrous air; thefe three fubftances differ from one another, only in the proportion of the oxygen to the azotic principle, of which the latter, the nitrous air, contains the fmalleft; but this has a ftrong tendency for faturating itfelf with oxygen whenever it can receive it from a furrounding body, as, e.g. the atmosphere; and hence it has been found ufeful for afcertaining the quantity of oxygen

gen gas contained in certain mixtures of gaffes, as in the atmospheric air, &c.; as may be feen from the publications of different authors, as Dr. Prieftly, Ingenhouz, &c.

The azotic principle combined with a due portion of oxygen, forms nitric acid; this has a ftrong difpofition to combine with many other bodies, as *e. g.* with alkaline falts, in combination with which it is found in certain plants and earths.

The azotic principle has alfo, when fet at liberty, an attraction for hydrogen; with which, when combined in a due proportion, it forms ammonia or the volatile alkali, a fubftance likewife found in fome plants, united with acids.

Azotic gas, or azote combined with heat, may be obtained free from oxygen, with which it is mixed in the atmosphere, by exposing to atmospheric air a body which has a fuperior elective attraction for the oxygen, and which will therefore abforb the oxygen; as for inftance, phosporus or heated fulphur. It is fet at liberty when mixed with fixable air, by the process of combustion

3

combustion of charcoal, or more difficultly by refpiration.

When combined with heat, it cannot fupport life nor combuftion; and therefore, its prefence, when not accompanied by oxygen, muft be more or lefs hurtful to animals and vegetables in the procefs of refpiration, &c; yet its other qualities foon prevent the bad effect which might arife from its prefence: As for example, its being lighter than atmospheric air, caufes it to rife in it, or to leave that part of the atmosphere where it has been deprived of the oxygen either by the process of refpiration or combuftion, and confequently, it is carried off from the place where it might have been hurtful to organized bodies, and have interrupted the process of combuftion.

Moft plants foon die when exposed in it, but there are fome which continue to grow in it, fuch as Lichen verticillatus,—L. aidelus,—L. radiciformis.—L. pinnatus, and most of the byffi; byffi ;—Agaricus acephalus,—A. aberuntius,— Boletus botryoides, &c; according to the obfervations of Mr. Humbold, and Scopoli.

CARBON.

CARBON.

THIS matter we confider as one of the principal conftituent parts of vegetables. And it appears, that it enters and accumulates in the conftitution of plants in proportion to their fucceffive growth.

Some plants however, take more into their composition than others, e. g. Agaricus quercus, -A. antiquus,—Boletus versicolor,—B. igniarius,—B. striatus,—B. perrennis,—Clavaria hypoxylon,—C. pistillaris, &c.; all these contain, from the refults of analysis, a quantity almost equal to all their other component parts; but others; as Lichen crispus, pinaster, granulatus, -Agaricus piperatus—Clavaria aurea,—Peziza agaricus, Lycoperdon tessellatum, contain a very fmall portion of carbon.

Carbon

Carbon is obtained from plants in its moft fimple flate by heat; namely, in expofing vegetable fubftances, excluded from the accefs of pure air, to fuch a degree of heat as to feparate all the volatile fubftances with which carbon is combined; in which cafe, all that adheres then to the remaining carbon may be a few earthy or fixed faline particles, which may be feparated from the carbon by water and acids.

From fome experiments it appears, that carbon in that ftate retains a certain portion of water, and according to Dr. Bancroft, alfo a portion of oxygen which caufes its black colour. When, therefore, carbon in that ftate, is expofed in a clofe veffel, and a great degree of heat applied, that portion of water may then be decompofed, and thus yield hydrogen gas, and likewife fixed air according to the new theory.

Carbon obtained from vegetables in the abovementioned process, is a black, light, opaque, matter, which is infoluble in water, and as far

23

as we know in any other fluid which does not enter into a new combination with it; it is further indeftructible by the mere effect of heat, and is not inflammable when excited by heat and light alone.

But, it has an attraction for combination with other matters; as for inftance, for oxygen affifted by heat; in combination with which, it produces the carbonic acid; and that, by the additional combination of fenfible heat, produces that elaftic fluid called fixable air or carbonic acid gas, which is the general refult of the combuftion of inflammable fubftances which contain carbon in their composition. In this ftate of combination it is abforbable by water, and thereby rendered fit to enter the conftitution of plants. For the knowledge of the properties of that combination, we are indebted likewife to the great Dr. Black.

It appears, from the refults of fome experiments, that carbon is a compound; and fome are of opinion, that it confifts of hydrogen and the

azotic

G

azotic principle; this fuppofition certainly deferves the attention of chemists, as in that cafe, we might be able to explain the formation of carbonaceous matter in plants growing in a fituation merely furrounded by fand, water, and atmospheric air, in which no carbon has been discovered; for even then, plants in the course of their growth obtain a great portion of that matter, in which case the water may be supposed to afford the hydrogen, and the atmosphere the azotic principle.

The editor of this effay, intends to enquire by experiment into the truth of this opinion, by expofing a plant to mere water and a fufficient quantity of atmospheric air free from carbonic acid, in order to find, whether, in the course of the growth of the plant, the quantity of azote is greatly diministed; and also to examine what quantity of carbonaceous matter the plant may then contain in its composition; in this experiment, it can easily be contrived to give an additional supply of oxygen gas if necessary.

However,

However, as it is, carbon may be uleful in many refpects in promoting the growth of plants. In the ftate of carbonic acid, it may ferve as a ftimulus, or as a fupply to plants: In its other ftate, it may ferve for feparating the oxygen from fuch combinations as furround plants, and which may have a noxious effect upon them; or it may promote the diffolution of old, and the formation of new, combinations.

In the mixture of carbonic acid and heat, as fixable air, on entering the refpiratory organs of living bodies, it foon extinguishes life; but, when introduced into the other parts of living bodies deftined for digestion, &c. it discovers beneficial qualities.

The noxious quality of fixed air upon refpiration and combustion, is however happily modified or prevented by one of its other qualities, and by the properties of other substances; in the first place, it is heavier than atmospheric air, and confequently, it occupies (when formed and fet at liberty,) the lower region of the atmosphere,

mofphere, and cannot thus exert its hurtful quality in that part of the atmosphere from which our respiratory organs receive their food, and from whence combustion is supplied; secondly, it is absorbable by water and different earths, by which it is therefore taken up and afterwards conveyed to those parts of plants, upon which it induces a beneficial quality.

THE earthy and faline particles, which are occafionally found in the analyfis of plants, feem not to be peculiar to their composition; as there are plants, in which we fearcely difeover any, and others again which contain a great quantity of them: So for inftance, earth is found in a great proportion, in hypnum crifta castrensis, and neckera dentroides; and Mr. Humbold found by an analyfis, that the chara vulgaris vulgaris, contained about ; of calcareous matter.

Earths probably enter plants, in a flate prepared by carbonic acid and diffolved in water; in this flate, earth may part again with the carbonic acid, by a new combination with the acid formed in vegetables, and may thus produce the vegetable felenite which is found in plants. Earths in which plants grow, may become very ufeful to them in many respects: As for inftance, by attracting and abforbing moifture or other nourifhing effluvia from the furrounding atmosphere, and communicating such to the proper parts or organs of plants in a due proportion, according as they may require it in the different periods of their growth : Farther, by imbibing the matter fecreted by the roots of plants, which might become hurtful either to themfelves, or to those growing near them; by abforbing and retaining the hurtful part of fome of their applied food, or other deftructive matter which their decomposition may produce.

Earth

Earth is likewife ufeful to plants, in preventing by its cohefive power a too rapid extension of their roots, fo that thefe may acquire a proper firmnes, both to fustain the different effects induced upon them by their furrounding medium, and to prevent, by its interposition, a too fudden effect upon them.

Earths have also the quality of imbibing such matter from the ambient atmosphere, as fixed air, which may become noxious to the different parts in the atmosphere.

Earths or foils become beneficial to vegetation, by their property of imbibing light falling upon them, by which fenfible heat is produced, which heat occafions a moderate evaporation of humidity, and difpofes fuch to enter the plants. This evaporation is attended with the production of a moderate degree of electricity, likewife ufeful to vegetation; and laftly, the heat thereby produced, becomes active in promoting a gradual diffolution and preparation

tion of their applied food, &c. Vide Article HEAT.

Other fubftances, as faline bodies, may be ufeful in promoting the growth of plants, by acting as a flimulus upon them when they are exhausted, or when they are too much excluded from the other general agents which excite and fupport their irritability, or may become a fubilitute of the abforbent earth, or modify a too ftrong cohefion of certain foils: As for inftance, the muriates and nitrates of alkaline fubftances, felenites, &c.

AMONGST all the above-mentioned fubftances which are neceffary for vegetation, we find water, in its fluid ftate and of a moderate temperature, is certainly the most effential fubftance; and not only, that its component parts enter into the composition of plants and their products, but that it likewife enters the veffels of plants

plants in an undecomposed ftate, extends them, modifies the heat, conveys their various foods to their different parts, and gives fluidity to the component parts of their juices, and thereby renders them more fit for circulation. It refreshes exhausted plants, acting as a stimulus; and lastly, it disposes the substances intended for their food to dissolution, as it is necessary, for fermentation, or putrefaction.

PLANTS.

57

mation

PLANTS.

PLANTS, placed immediately after animals, conftitute the fecond class of organized bodies.

The more we inquire into the economy of plants, the more we difcover a fimilarity between them and animals. Plants live; they originate from bodies of their own kind in an uninterrupted fucceffion; they affume various forms fucceffively, from the firft moment of their exiftence and life, till their final decay; they contribute to their own growth and prefervation, by receiving foreign fubftances into their bodies through their veffels or organs. Thefe received fubftances are changed by the peculiar internal operations of the plants, and are therein prepared, partly, to enter into their proper conflitution, and partly, for the purpofe of the for-

mation of their products, which become thereby different from the component parts of the plants themfelves, and different alfo from the nature of the fubftances which they had received from without. Plants die, that is, their organs are deprived of the power of receiving food, and of preparing it for their further existence.

Plants like animals, experience three different periods in the course of their existence; viz.—origin or beginning,—-formation,—-and death.

Death is attended with a decay of bodies, and this again with a feparation, diffolution, and decomposition of their conflituent parts; which thus follow the laws of chemical attraction and combination.

The living body is indued with a peculiar internal power, which occafions a diffolution of the attraction of chemical combination, and which prevents the principles of bodies from acting upon, and from combining with each other,

58

ther, according to the law of chemical attraction.

The fubftances of which organized bodies are composed and conftructed, when these bodies are living, follow the laws of their natural impulse of figuration, (*nifus formativus* of Blumenbach), which impulse exists in all organized bodies, and causes each of them to assume and preferve their peculiar stapes.

The diffinguishing marks for the two general claffes of organized bodies, are derived,

1/l, From their organs or parts for receiving food.

2d, From motion.

(Blumenbach, Hanbuch der Naturgesch. §. 3. 4. & 170.)

All bodies which receive their food through more than one channel or mouth, and which are defitute of the power of a voluntary extension and contraction of parts, are arranged under the division of plants.

Life

Life fignifies the uninterrupted motion of organized bodies.

In plants we obferve,

1/t, An uninterrupted motion which is caufed,

a. By the vital power.

b. By external fiimulus.

2d, Uninterrupted motion, occafioned by an internal ftimulus; as for inftance, the motion of the *ftamina* towards the *ftigma*, and the receffion from the *fligma* before and after impregnation in the parnaffia *paluftris*, $\Im c$.—Vide Mr. Humbold's obfervations on the ftamina of the parnaffia *paluftris* in *Ufters Annales* of botany, N°. 3.

Another example of the fame nature, and which will be referred to when treating on the irritability of plants, is, that most of the water plants rife or move to the furface of the water when about to bloom, and fo fink, or are immerfed again, as foon as they are impregnated; fuch we observe in valifneria; the

60

the female flower of this plant is fixed upon a long fpiral ftalk, when the time of the bloffoming approaches, the ftalk unwinds, and raifes the flower above the furface of the water; the male plant produces a number of flower buds under the water, thefe grow upon flort and ftraight ftalks, but when about to blow, they feparate or detach themfelves from the ftalks, and rife to the furface of the water, where they fwim and burft or unfold, and then impregnate the female flower; which, after the impregnation, returns again under the water.

3d, Interrupted motion occafioned by external ftimulus; as for inftance, in the mimofa *pudica*, dionæa *mufcipula*, oxalis *fenfitiva*, &c.

In the ftricteft fenfe, vital power is the caufe of all motion, it only manifefts itfelf varioufly, according as it is excited, or brought into activity, by external or internal ftimulus, or by mechanical powers.

Though plants generally feem not to be capable of moving from their fituation, or to be ftationary, tionary, yet there are exceptions; as, for inftance, the *lemna*, which changes its ftation.

Like plants, there are alfo animals, as the lepus *balanus*, aftrea *edulis*, and lernæa, which are incapable of changing their fituation; hence, the capacity of organized bodies, of changing the flation, is not peculiar to animals alone.

If we take it in the ftricteft fenfe, we may appropriate a moving power to feveral plants; as ajuga *reptans*, glecoma *bederacea*, and cufcuta *europæa*.

There are many inftances in which animals refemble plants; as, for inftance, we obferve that many infects begin and finish their course of life with the close of one summer, like the annual plants. As to the propagation of separated parts of plants, we observe similar instances in parts separated from animals, as polyps, and other aquatic animals.

Uninterrupted motion, we confider as a doubtlefs characteriftical mark of living bodies. This we obferve in animals and plants; both difcover difcover more activity in the spring than in winter.

The total interruption or fufpenfion of life caufes death. Though the motion of many plants is fcarcely, or often not at all perceptible in the winter feafon; yet it would be contrary to all experience, to fuppofe that plants fhould then ceafe to live, if nothing elfe has occafioned their deftruction.

We know that plants, like animals, receive and excite matter of heat, and that both manifeft fenfible heat. Later difcoveries have alfo proved, that plants emit or yield matter of heat even in the winter feafon.

The moift atmosphere which we perceive in the fhade under trees, probably originates, not merely from their being excluded from the light of the fun, but becaufe the trees attract and imbibe a great portion of matter of heat, by which the water thereby held in the atmofphere is deprived of its elasticity, and is thus made to feparate in the flate of moifture.

Plants

63

Plants may receive heat from the furrounding atmosphere, by imbibing the air, and partly decomposing it, and also from their food during the digestion. Buffon and Hunter have proved the fact, that plants have a power of producing fensible heat.

THOUGH plants receive their food through various canals or mouths, and do not collect them in one refervoir like animals; yet, the mode and effect of their digeftion refembles much that of animals. They part like animals, with the fuperfluous and ufelefs matter; and this feparation they effectuate, not only by their refpiratory organs, the leaves and ftems, but alfo by other fecretions fimilar to what we obferve in animals.

Mr. Humbold, a gentleman of great reputation among the learned in Germany, has obferved, that plants really fecrete impurities through the extremities of their roots during the night, which excrements may, like those of thofe of animals, prove fometimes ufeful, fometimes hurtful, to other neighbouring plants. "Sie "læditur," fays he, "avena a ferratula *arvenfi*, "triticum ab erigero *acri*, linum ab euphorbia "*peplo* et fcabiofa *arvenfi*, polygonum *fagopy*-"*rum*, a fpergula *arvenfi*, Gc." From this he derives the effect of fallowing, and the harmony among plants.

It is a well known fact, that fome trees will not grow well near others, or that the one is hurt or fuppreffed by another of a different kind. The caufe of this was thus explained, that the one deprived the other of its neceffary portion of food; but Mr. Uflar fuppofes, with much plaufibility, that the fecreted matter of one kind of plants or trees, may likewife add to the caufe of the deftruction or injury of others. There are plants which do not allow others to grow near them, and which feem to prefer a folitary life. This circumflance has given rife to a divifion of plants, into Sociatæ and Soli-TARIÆ. Similar antipathy we obferve likewife

I

among

among animals; as certain different genera of animals will not live together in harmony.

Mr. Uflar is opinion, that this partly arifes from phyfical caufes; as he obferved, that certain animals cannot bear the effluvia of others.

Though certain plants flow a great antipathy to one another, yet there are fome which affift the growth of others. So, for inftance, we find the birch often nourifhing the oak and the beech.

PLANTS and animals perfpire liquid and permanent elaftic fluids. The exhalation from certain parts of animals varies refpecting the quantity and composition of the matter perfpired; the fame we observe refpecting plants.

The caufe why certain parts of plants produce conftantly the fame juices and exhalations, lies probably in the peculiarity of ftructure of the organs, difpofed in the various parts of living plants.

3

With

With refpect to propagation, we observe again a fimilarity in both classes of organized bodies, in the more natural mode of propagation, and in the production of mules or hybrids.

With respect to the production of hybrids, the following laws are common to both:

1/t, Only fuch plants and animals are mifcible, as have natural affinity to each other; hence, neither hens and rabbits, nor oaks and pines are mifcible.

The affinity of plants is not always to be determined by their external form; not unfrequently we must afcertain it by the fimilarity of their pollen.

2d, The hybrid approaches always to the male, in the fubfequent generation. In regard to the parts of generation, we obferve great differences between animals and plants; those of the former are permanent, and those of the latter are reproduced for every fucceflive generation.

How nearly plants approach to animals refpecting

fpecting their copulation, &c; we may fee from the obfervations contained in the valuable differtations of 'the great HEDWIG, viz. his Hiftory of Moffes, and Account of the Fructification of the Cryptogamic Plants.

Winter fleep or reft, is common to animals and plants; during this time the action of their organs does not ceafe, it is only modified.

To the analogy between plants and animals, we may add the power of reproduction.

a. Reproduction of parts loft by the natural difpolition which is common to both; viz. in animals, the fall and reproduction of hairs, feathers, and horns, in the autumn and fpring; in plants, the feparation and reproduction of the cuticle and leaves.

b. The reproduction of parts accidentally deftroyed, to which we refer the confolidation of wounds.

The caufe of reproduction was generally attributed to the prefence of a number of original embryos, exifting or previoufly difperfed through the

68

ON PLANTS.

the body, and which are occasionally evolved, if there be a fufficient fupply of food, &c.

The excellent Phyfiologift, Profeffor Blumenbach of the University of Gottingen, however, has favoured us with a different and very ingenious theory; according to him, there exift no preformed embryos in organized bodies; but he alleges, that in the prior unformed generative matter of organized bodies, after it arrives at maturity, and has reached its fixed and deftined fituation, a peculiar and continually acting impulfive force is fet at liberty, and caufes this matter to acquire or affume a certain form at first, and to preferve the fame afterwards; fo, that if fuch form be injured or loft, it may be repaired or reproduced. This impulse or impulsive force is connected with the vital powers, but equally and evidently differs from contractability, irritability, and fenfibility, as well as from the common phyfical powers of bodies; and it appears to be the first, and most effential instinctive power neceffary neceffary for generation, confervation, and reproduction.

NISUS FORMATIVUS OF BLUMENBACH *.

OF THE

THERE are two theories known of generation and reproduction. The one is diffinguished by the name of Epigenesis: by this it is maintained, that when the mature, but crude and unformed generative matter of the parents, reaches the place destined for its reception, at the proper time, and under the necessive circumstances, it is then gradually formed into a creature.

The other theory is diffinguished by that of Evolution. This theory denies all generation of the organized world; it contends, that nature had at once produced the embryos for all animals

* Vide his treatife on that fubject.

70

animals and vegetables, which ever have lived, and which ever fhall live, at the first creation; fo that now nothing is neceffary for the production of these, but a fucceffive evolution of the embryo. To this theory Mr. Blumenbach makes very strong objections, as may be seen in his treatife on generation, lately translated into English by Dr. Crichton of London.

Blumenbach remarks, that many unorganized bodies affume a regular form when properly difpofed for it, as we obferve in the cryftallifation of falts, and various other fubftances. Though this power or caufe is different from the impulfe of figuration of organized bodies; yet it is evident, that there muft be fomething which has the power, or which caufes the fame bodies to affume the fame regular form under the fame circumftances.

In order to perceive the effect of the impulse of figuration most distinctly, Dr. Blumenbach chose fuch organized bodies for the subjects of his observations, as have a considerable fize, yet

yet are almost transparent and grow very fast. In these he was enabled to observe even the interior change and operation of their formation, c.~g. conferva *fontinalis*. This vegetable being is well known to botanists; it confists of a fingle, almost straight, short, and straight almost straight the fine hair-like matter which we observe in the spring in wells, &c. confists of a great number of these plants, which have shot forth and straight their roots in the mud.

The propagation of this plant thus proceeds; the extremities of the threads fwell, and form fmall tubera or heads, which gradually feparate from the mother threads, and attaching themfelves to fome particular fpot, they grow in a fhort time to a perfect thread. The whole progrefs of their formation can be obferved in the courfe of 48 hours.

Dr. Blumenbach could not discover, by the aid of the best magnifying glasses, any trace of an involved embryo, &c.; he made also fimimilar milar observations on a certain kind of polyp.

The refult of his obfervation was, that;

1/l, The impulse of figuration proceeds rapidly in early life, flowly and more perfectly in advanced age.

a. By the generation of the foetus;

b. By the reproduction of parts on the formed bodies of plants and animals.

2d, The power of figurative impulse varies;

- a. In various parts of the body;
- b. In different bodies.

In like manner, we observe diversity respecting irritability in certain parts of plants hereafter to be treated of.

3d, The impulse of figuration, or Nifus Formativus, takes fometimes a preternatural direction; in which case there are produced,

- a. Heterogeneous forms, as horns and hairs; or, in plants, we obferve leaves refembling those of a different species.
- b. Preternatural forms, as monfters.

K

The

The caufe of fuch deviation we cannot inveftigate. Inftances of it more rarely occur, however, in wild and unconfined animals, and more frequently in fuch as are confined or domefticated; for climate and food, both feem to have great influence in caufing fuch deviations.

ORGANIZED BODIES CONSIST;

1/l, OF folids; 2d, Of fluids. The latter are,

a. Liquid; or,'

b. Permanently elastic fluids.

Carbon, hydrogen, azotic principle, and oxygen, are the chief principles of plants.

The folid mass of fuch bodies is partly organized, partly destitute of organization.

Every living creature is provided with various veffels

veffels and inftruments, neceffary for its propagation, prefervation, and for promoting its periodical growth; thefe conftitute its organized part.

The organs of animals and vegetables have, or affume, a determined ftructure, which does not depend on accidental causes.

The folid parts of plants Mr. Uslar divides into,

Ist, Primitive folid fibres, which he calls fa-

2d, Simple fibres.

By primitive fibre (fafer), he means the unorganized matter; it is the whole corpufcular mafs, which poffeffes the vital power only when in connection with the organized parts; the use of it is, to connect the smallest fibres, and those veffels which are more or less compofed of them, to cover them, and to fill up their interflices.

The whole unorganized mass Mr. Uslar calls cellular

cellular web; what BORDEU calls tiffu muqueux.

All folid parts of plants are formed of one and the fame matter, Cellular Matter. This probably originates from gelatinous juices, in combination with other principles; by the acquirement of it, all forms are generated; hence the appearance of organization, in unorganized parts.

The fimple parts of the organized mafs confift of fibres. "Solidarum partium in anima-"libus et vegetabilibus communis eft ea fabrica, "ut earum elementa, quæ fubtiliffima micro-"fcopium attingit, fibræ fint.—HALLER."

Fibres, as far as we have been able to difcover their most fimple state, are thin cylindrical lines; their matter is cellular web.

The folidity of the fibres, as well as that of the whole organization, depends on the denfity of the cellular web, that being the matter of which they were formed; and the denfity of the cellular web, depends upon the clofe, or loofe condition condition of the imaginary fimple fibres of which that is again composed, as well as from the intimate connection of those parts among themfelves.

By the combination of fibres veffels are formed; this is the fecond ftep of organization. The third ftep confifts in the connection of certain veffels, of which compound organs or inftruments are formed. It appears, that a very intimate combination among the organs of organized bodies takes place; elfe confiderable injuries of parts of plants would immediately caufe their deftruction or death; which, however, is feldom the cafe. According to Mr. Uflar's opinion, the combination of fibres, veffels, and inftruments, is produced,

- a. Directly by the unorganized mafs.
- b. By the interweaving of very minute branches, whofe extremities terminate in open mouths.

Simple as the ftructure of plants and their organization

ganization appears, yet we obferve a great complication in the connection or composition of the fibres of the cellular web. This has been fufficiently obferved and shown by physiologists; and any body may easily convince himfelf, by the aid of a magnifying glass, that each genus and species of plants has something peculiar in the connection of the fibres of the cellular web; and that the proportion of the vessel varies as to fize and number; it hence naturally follows, that the preparation of the received alimentary juice must thereby be variously altered or modified; and thence the great variety among vegetables may originate.

In the animal body we difcover two different kind of fibres,

1/t, The fenfible or nervous fibres; of which the nerves of animals are composed. We shall hereafter observe, that fensation depends on nerves, a property of which plants are destitute, according to the general opinion. In so far as we understand by fensation, the perception tion of external things, and the fusceptibility of pleafant and difagreeable impressions, we may confider plants to be destitute of that sensation.

Animals poffers the property of fenfation in very different degrees. In many of them we difcover it in a very inferior degree; fo that the motion by which it becomes manifeft, appears to refult merely from a ftimulus acting directly upon the irritable fibre, like what we obferve in plants.

Mr. Uflar does not choofe to compare this to the motion which is caufed by the irritability of plants, though fomething might be deduced from it, which may fhow the clofe analogy between the inferior tribes of animals and plants. The nervous fibre has not yet been difcovered in plants; and the want of fenfation, taken in the ftricteft fenfe, affords already the analogical conclusion of the abfence of this fibre.

2d, Another kind of a fibre, totally different from

from the foregoing, is the mulcular fibre, (*fibra irritabilis.*) This is common in all organized bodies. It exifts in plants as well as in animals. It not only caufes the motion; but it is alfo the material caufe of life, in fo far as we confider irritability as a vital principle of organized bodies.

The power of contraction, in organized bodies, depends on the irritability of the mufcular fibre; that wherever, therefore, we obferve a contraction of the parts to which a ftimulus is applied, we may fafely conclude the prefence of mufcular fibre in thefe parts. Haller fays, that, in many cafes, we difcover the exiftence of mufcular fibre in certain parts, more by its effect, than by our organs of vision.

If the caufe of contraction, obferved after applied ftimulus, lies in the irritability; and if it is true, as it really appears to be, that only the mufcular fibre poffeffes irritability; it is then not difficult 'to prove the exiftence of irri-table fibres in plants; by vifible perceptions.

I

80

It

It is well known, that the leaves, ftalks, and stamina, of many plants manifest irritability, or contract when touched ; e.g. the leaves of drofera longifolia, drofera rotundifolia, dionæa mufcipula, averrhoa carambola, mimofa, &c. the ftamina of the cactus opuntia, and feveral other fpecies of that genus, the stamina of berberis vulgaris, heliotropium, parietaria officinalis, lilium fuperbum, calendula, martynia annua, and feveral of the urtica genus, as, for inftance, urtica dioica. On this fubject we have a valuable differtation by Mr. Medicus, Prime Counfellor, &c. Of the Inftinct of Plants for copulation, in Hift. et Comment. Acad. Theod. Palat. Tom. III. pag. 116, et feq. and alfo by Des Fontaines, on the irritability of plants in general, Bonnet, Brouffonet, Hope in Differt. quædam de Plantarum Motibus et Vita complectens, Edin. 1787; and Gmelin de Irritabilitate Plantarum.

This may fuffice, for the prefent, to prove the existence of irritable fibre in plants, or in all

L

organized

organized bodies; more will be faid upon this fubject in treating of irritability, in particular examples.

Mr. Gritanner, by his experiments, endeavours to prove the existence of three different kinds of irritable fibres.

1/t, The Straight Fibre (recta), which contracts longitudinally, or in Iuch a manner, that the extremities approach each other.

2d, The Spiral Fibre (*fpiralis*), by the contraction of which the diameter of the veffels which are formed by it is diminished.

3d, The Circular Fibre (circularis), generally difcovered at the extremities of veffels; the apertures of which it clofes by its contraction.

The contractility of the irritable fibre manifefts itfelf after an applied ftimulus. But there is a difference in the effect of the contraction, according to the different external form of the fibre; and alfo, with respect to the velocity with

ON PLANTS.

with which the ftimulus is received. The contraction of the ftraight fibre takes place quickly, or even inflantly throughout the whole fibre, as foon as one of its parts receives the ftimulus; from which it may be concluded, that these straight fibres exist particularly in those parts of plants, the contraction of which takes place immediately and perfectly; as, for inflance, the leaves of dionæa muscipula, and mimola pudica. The contraction of the circular fibre takes place more flowly and gradually; that of the fpiral fibre is floweft of any. The ftimulus which is quickly communicated from every part of the ftraight fibre to the others, proceeds but flowly in the circular and fpiral fibres; it is communicated fucceffively to their different parts; and manifests corresponding effects. This contraction of the fpiral fibre has been called Periftaltic Motion; and Malpighi was perhaps the first who discovered it in the spiral vessels feparated from the stem; it is likewise found in the intestines of animals.

THE

THE VESSELS AND INSTRUMENTS, OR ORGANS OF PLANTS, MAY BE DIVIDED INTO;

1/t, ORGANS for fecretion ; 2d, Organs of motion.

Earther, according to HEDWIG, with regard to the direction in which they move their contained juices.

- a. Either from the ftem towards the branches, (adducentia.)
- b. Or from the branches towards the ftem and roots, (*revebentia*.)

Moreover, the organs of plants may be divided into those which;

1/l, Serve for the continuation and prefervation of life;

2*d*,

2d, Effectuate the propagation and generation of the germs of new bodies of the fame kind.

For this purpole it appears, that all the organs and fingle fibres harmonioufly unite their powers. Harmony manifeftly exifts in the whole creation; by it all nature is concatenated; the more therefore may we prefuppole it in the ftructure of any fingle body.

In the more particular diferimination of the various veffels, Mr. Uflar follows the famous Mr. Batfeh; he confiders them as,

- a. Utricles, (utriculi), which are produced or adhere horizontally;
- b. Succiferous, or fap-veffels (vafa fuccofa), which proceed longitudinally in plants; thefe may be divided into,
- a. Pith-veffels, (vafa medullaria), which are chiefly found in the medulla;
- b. Nutricious-veffels, (vasa propria, nutrientia;)

¹st, Filamentous.

c. Lymphatic-veffels, (lymphatica.)

2d, Spiral veffels; they confift of flatted fibres or threads, of an equal breadth, which are wound or coiled up in a fpiral manner, fo as to form a tube; (tracheæ, vafa aërea or fpiralia).

Meffrs. Grew and Reichel confider them, contrary to Malpighi's opinion, as confifting of feveral fibres, whereas the latter confiders them as made up of a fingle fibre.

They are found for the moft part underneath the bark, and frequently under the cuticle of fuch plants as have no proper cortical ftrata; as, for inftance, the graffes; they are very irritable, and contract by an applied ftimulus.

Malpighi reprefents, that thefe veffels are conftantly filled with air, and that they refemble the tracheæ, or air-veffels of infects; Mr. Grew, on the contrary, afferts, that they contain occafionally different juices. Their great ufe is to ferve as refervoirs for air; but modern phyfiologifts afcribe fome other qualities to them : Linné Linné thought that he had difcovered the living power of plants to refide in the medulla or pith, and that the production of the corculum or rudiment of new plants was derived from it; this however, at prefent is believed to be produced by the *fiftulæ fpirales* *.

The before-mentioned fuppofition feems to be very probable; for how fhould it be poffible, that plants, or hollow trees, which have loft the greateft part of their pith or medulla, as we frequently obferve on the old ftems of willows, &c. fhould be able to produce new parts, *e. g.* buds, and feeds, and fhould continue to grow as vigoroufly as if they contained all their pith.

The claffical writers on this fubject are; MAL-PIGHI, GREW, in the Anatomy of Plants: Bon-NET,

* The neceffity and efficacy of thefe fpiral veffels, is fufficiently and ingenioufly demonstrated by HEDWIG, in a differtation on the Origin of the Male Parts of Fructification of Plants; and likewife, in another, in which he has answered the question'; What is properly the Root of Plants?

NET, Recherches fur l'Ufage des Feuilles dans les Plants: BAISSE de Vafis Plantarum. In which Jampert's opinion, against the probability of the existence of vessels in plants, is refuted.

Indeed, natural appearances, and the refults of many microfcopical examinations, feem to prove fufficiently, that plants have veffels.

The UTRICLES feem to be intended for containing the juice or fap, and probably likewife for affifting in the preparation of it. The formation of the vegetable juice is too fubtile an operation to be demonstrated or imitated by chemistry. For, notwithstanding the many opinions which have been fuggested respecting the interior oeconomy of plants, we are still much in the dark with regard to it; we know little of the more minute combinations and structure of organized bodies, but still less do we know of their internal operations.

WE

We may fuppofe, that plants like animals have,

1/t, Соммон juices, which are diffused through all parts of their body.

2d, PARTICULAR JUICES, which are found only in certain parts, and are probably fecreted from the firft. They are contained therefore in particular fecretory veffels. One part of the juice thickens, from time to time adheres to the folid fibre (fafer) of the cellular web, increafes thereby the mafs, and thus promotes growth. In this manner the origin and formation of new ligneous fibres may be explained.

In order to underftand how the nutritious liquid received by plants, and the juices fecreted by them, can appear in fuch different forms or ftates; as a folid body in the woody plants; as a compact inflammable matter; and how the aqueous liquid is changed into vegetable juices; recourfe muft be had to the firft part of this treatife.

We

We know, that bodies may affume various flates; they may pafs from a folid to a liquid, and from a liquid to an elaftic fluid flate, folely by means of heat.

The nutritious water in plants may change its liquid ftate to an elaftic fluid, in two ways;

a. By the accumulation of heat; or,

b. By decomposition.

By decomposition, the two conflituent parts, the oxygen and hydrogen, are feparated from each other. The hydrogen enters into a new combination with the vegetable matter; the oxygen is fet at liberty, and escapes in the state of oxygen gas by means of light. Light acts, partly as a stimulus upon the leaves and upon the green coats of the tender stems, partly as a matter having a straction for the oxygen, and thereby effectuates the formation, and subsequent escape of the oxygen gas.

All elaftic fluids are condenfible; the hydrogen appears to exift combined in plants in a ftate of condenfation. Hydrogen, or hydrogen gas,

90

gas, is, as we know, inflammable; and by its combination with oxygen gas flame and fenfible heat are produced; the latent heat of thefe fluids being difengaged in confequence of the greater attraction of the oxygen for hydrogen.

Newton's fuppofition, that water is a body, intermediate between an inflammable and noninflammable fubftance; that water is neceffary for vegetation; and that plants receive their inflammable matter from it, is now verified by experiments and facts. By the difcovery of the compofition and decomposition of water, much light has been thrown upon the nature of plants. Another portion of their inflammable matter, plants may obtain from the atmosphere, by the absorption of air and effluvia therein contained.

The matter with which the hydrogen, when feparated by the decomposition of water, is combined again in plants, feems to be carbon. A great quantity of carbonic acid gas is constantly produced by the respiration of animals, mals, by fermentation, by various decompositions, and by the combustion of vegetable fubflances.

There are even plants which emit carbonic acid gas, viz. falix viminalis, pinus cedrus, quercus robur, betula alba. We know, as obferved before, that this gas is fpecifically heavier than atmospheric air, in confequence of which it finks towards the furface of the earth, which it gradually enters; it is then conveyed to the roots of plants, and thus becomes beneficial to them. It appears, that plants receive and have the power of decomposing carbonic acid gas in like manner, as they receive and decompofe water.

The following fimple experiment will fuffice to fupport this opinion.

Plants yield oxygenous gas when exposed in the fun: If two branches of a plant are immerfed, the one in common water, and the other in water impregnated with fixable air or carbonic acid; we then find, that the branch immerfed in

92

in the latter liquid, yields, under the fame circumftances, a greater quantity of oxygenous gas than the other. The difference in fome experiments has been found in the proportion of 264 to 1. The proportions vary however, when different plants are fubjected to trial, fo much, that no general law can be eftablifhed. The carbonic acid, with which the water is impregnated, is decomposed then by the branch, the carbon enters feemingly into the conflitution of the plant, while the oxygen is fet at liberty, and flies off, more or lefs of it, in the ftate of gas.

Plants do not, however, retain all the carbonaceous matter which they receive; they obtain more in the courfe of the day when acted upon by light, than they naturally require. By the abfence of light, plants lofe part of this carbon, as during the night; hence, the caufe, that plants yield refpirable gas only in the day-time, particularly when the fun beams fall immediately upon them; and that plants

plants do not yield pure air in the night, but frequently at that time give out bad air.

That water, or its component parts, afford the principal aliment for plants, not only appears from their quick growth after an electrical rain, but alfo, by the quick formation and growth of many fungi, viz. clavaria fastigiata, agaricus campestris, &c. The opinion, that these fungi were formed by fermentation and crystalifation from the mucilage of other vegetables, is fufficiently refuted by the ingenious Mr. Wildeno. Later discoveries in-chemistry. have enabled us now to understand the various combinations and decompositions which may take place of fubftances which enter plants; that the more fimple fubftances not only may affume different forms, but that they may change likewife their properties when combined with each other in various proportions, has been explained in the former part of this treatife.

Of

94

OF THE SUCCESSIVE INDURATION OF CERTAIN ORGANS OF PLANTS, OR THEIR CHANGE INTO WOOD, AND OF THE DIFFERENCE AMONG PLANTS.

FROM the phyfiology of animals, we know, that;

1/*i*, The living body in its infancy, confifts of more fucculent parts than in older age, and that the folid parts increafe with every year in the courfe of life, to a certain period, when they attain their perfect ftate.

2*dly*, That, by the conftant exertion, many organs are weakened or become lefs active; many parts are condenfed by preffure, as well as by attraction of cohefion. Some of the fmall veffels lofe thereby the capacity of tranfmitting the juices, others are deprived of their extenfibility; this occafions

cafions the cavities to be filled up, the rarer parts are changed into folid web, and by this again many veffels are clofed. The irritability is diminifhed by age, fome parts are entirely deprived of it, and they remain uncorrupted or alive, only in as far as they are ftill connected with other found and active parts.

These observations applied to plants, make it likewise comprehensible, how their organs or parts may be changed into solid and woody fibres (fasern).

The refult of all these changes is the death of the parts. The quantity of juice diminishes, as parts become more compact and folid; the absorbent veffels gradually fuffer; and becoming unfit for their functions, the nourishment is thereby diminished.

OBSERVATIONS

96

OBSERVATIONS ON THE IMPORTANT QUESTION, WHAT CAUSES THE GREAT VARIETY OF THE INTERNAL AND EXTENAL CONSTRUCTION OF PLANTS?

ist, THE first cause lies in the organization. The main body or general mass, we observe, has a different structure in different plants. Not only the construction of the folid fibre of the unorganized part (contextus cellulofus), varies with respect to density, &c. ; but also the form of the organs, of the juice veficles, &c. the structure of which, and thinnefs of their coat, enables them to fecrete more or lefs of the elementary conftituent parts of their nutritious juice in a variety of ways : So that we may almost confider them as inftruments for chemical operations. We find that some are more fit for the fusception, rarefaction, and preparation of food, than others. There is no doubt, but that the diffolution, fe-N cretion,

cretion, affimilation, &c. of the principal conflituent parts of the nutritious juice, prefuppofes a varioufly modified, but determinate ftructure of the different organs.

2*d*, Another caule of the variety, lies in the altered flate of the received food, and in the different proportion of mixture.

Water and atmospheric air are the fubftances which afford plants what they principally require for vegetation. Though fimple these fubftances appear to be, yet we know, by the aid of chemistry, that they are not only compofed of the most efficacious elementary fubftances, but also that they contain a variety of heterogeneous matters.

Oxygen, hydrogen, and carbon, feem to conflitute the main aliment of plants; a great portion of the two laft is taken up by the veffels, and combined in them with the vegetable matter. Earth appears not to be a neceffary component part of all plants; for by the analyfis of many vegetables, fuch as the byffus, peziza, and

98-

and feveral other cryptogamic plants, particularly of the genus of fungi, we find no earth in their mixture; and though there are plants which contain more or lefs earthy parts, particularly calcareous earth, yet this does not prove that earthy parts are neceffarily component parts of plants.

A great number of experiments, both of earlier and later periods, have flown that plants do not immediately obtain the requifite earthy particles from the foil in which they grow, but that they receive fuch from water and the atmosphere.

Hales, Bonnet, and others, have afcertained thefe facts directly by the increafe of weight; and how would it otherwife be poffible, that an oak could vegetate ten years in water, and its mafs continually increafe. Nature prefents fimilar inftances, and fhows by parafitic and pfeudoparafitic plants, that the earth or foil upon which they grow, does not afford them pabulum, but that they receive their earthy particles by other channels.

We

We frequently find plants (which Mr. Uflar calls Pfeudo-Parafitic plants), upon fteril and naked rocks, upon walls, &c. viz. rubus idæus, vaccinium vitis idæa, rubus fruticofus, which by accident are often found upon the ftems of old decayed trees, and continue there their growth.

Mr Uflar found that plants would grow in mere pounded quartz; not only herbaceous plants, as lepidium *fativum*, or refeda *odorata*; but alfo fhrubs, the heliotropium, *e. g.* grew particularly well. The infoluble particles of quartz could ferve here as only a fixed place for those plants, and as a refervoir of the water.

The fuppofition, that plants in fuch cafes were nourifhed by the heterogeneous, earthy, and faline particles contained in the water, and not by the water itfelf, is fufficiently refuted by Mr. Hoffman; who by very ingenious experiments found, that plants grew in diffilled water and air; (which are defcribed in Green's journal.)

This eminent Botanift accidentally obferved, that that a plant, mentha *crifpa*, growing in a glafs with water, had fhot out roots; this immediately engaged his attention, and led him to the following experiment, he put the fame branch in diftilled water, and found that the plant did not only continue alive throughout the winter; but alfo, that in fpring it began to pufh forth buds, which produced branches, flowers, and feeds.

In order to examine the juftnefs of Mr. Von Beunie's, and Spallanzani's affertions; that not only water and fixed air, but alfo feveral earths, particularly lime, marle, clay, promote the growth of plants; and that indeed water did not fo much itfelf affift vegetation, as the oily and faline parts contained in it; Mr. Hoffman employed, in the following experiments, water which had been previoufly freed from all heterogeneous parts by diftillation.

Having cut off a fmall branch of mint, weighing one dram and fifty grains, he placed it in a phial containing 8 ounces of diftilled

tilled water, and fecured the mouth of the phial with a waxy cement, fitted clofe alfo round the ftalk, fo that no water could escape at this place, nor any heterogeneous matter get into the phial. The phial with the plant was placed in a large room, and after 10 days, he perceived already fmall roots fhooting out from the lower joint of the branch which was immerfed in the water; these increased in number more and more; after 14 days he cut over the branch above the fecond joint which was without the phial; the part thus feparated weighed I dram 15 grains. Three weeks after, new buds began to fhoot out from this joint, between the two leaves and the flalk, and these grew out into branches fimilar in fize, form, and odour, to those commonly produced on this plant.

After fix weeks, all the eight ounces of water were confumed, and the plant had altogether increafed in weight eight foruples, or two drams and forty grains.

The phial was again filled with diffilled rain water,

ON PLANTS.

water, and the fame experiment repeated. The evaporation of the water in these experiments could only proceed through the plants; the confumption of the water varied, according to the temperature and the intenfity of the light to which the plant was exposed, and likewife, according to the different state of vegetation; for, in the firft days, before the buds were apparent, the quantity confumed was only 10 grains in the fhade; but, as the growth advanced, the quantity of water confumed alfo increased from 10 grains to feveral fcruples in the fun, often to two drams. At the approach of autumn, the perspiration diminished and gradually became imperceptible; at the fame time, the leaves of the plants became relaxed and loft their colour. The water then is confumed only during the growth of the plant; it therefore feems probable, that the water in this process has undergone a decompofition to promote the growth.

The weight of both branches which had been produced in the latter part of the experiment,

ment, amounted to two drams; and nothing but water and air could in this cafe afford pabulum to the plant, or the matter of which its parts were formed. Hence, therefore, the decomposition of water by vegetation, and the combination of its conflituent parts with vegetable fubftances, may be fairly deduced.

The caufe why all plants will not grow upon the fame ground, depends probably on the capacity of the foil to receive the food, and to retain it for the proper time.

Succulent plants require generally a moift foil; fuch, c. g. as fhall confift chiefly of garden mould, or the earth of decayed vegetables: For this not only imbibes the water eafily, but likewife retains it very long. Such foil is, however, often adverfe to the growth of other plants.

That plants receive their food from water, has been also lately confirmed by Von Marum; who also repeated the observation, that plants extend their roots towards moisture.

Trees

104

Trees growing near the banks of rivers, extend their roots, particularly towards the water; and if a moift fpunge is laid near a fide root, we obferve, that the root is attracted, as it were; by the moift fpunge, as iron by a magnet.

Leaves appear to be the moft neceffary inftruments for fupporting vegetation. They anfwer not only the purpose of receiving food, but likewise the purpose of lungs, for respiring and perspiring air or other elastic fluids.

Plants which have a confiderable foliage, perfpire more than those with few leaves.

If we take two branches, and deprive the one of its leaves, we then find,

1/t, That that branch which is defitute of leaves, does not take up fo much water as the other which has its foliage entire.

2*dly*, That the first becomes nevertheles heavier than the latter, by reason that the water which it absorbs is not decomposed by it, but remains for the greatest part within it in an un-

0

altered

altered flate : while, on the contrary, the other, though it retain most of the hydrogen, retains only a fmall part of oxygen, emitting the greateft part of the latter in the flate of gas, by the effect of light. Trees, therefore, with much foliage, feem to require a more humid foil than those with less foliage. This is generally indeed observed to be the case: but there may be now and then exceptions, for some plants perspire less than others. The difference some to proceed, partly from their internal structure, according to Mr. Uflar; because the trees of hot climates, which have much foliage, do not perspire as much as those of more temperate climates.

A lemon tree, for inftance, perspires in proportion less than acer pseudo-platanus or sycamore.

The external form of the leaves is alfo different and may have effect on the perfpiration. The leaves of the lemon tree are entire and fmooth: whereas, those of the fycamore are angular, and their

JOD

their under furfaces are covered with fine hairs, which are probably intended for perfpiration.

As the external form of parts affifts perfpiration; in the fame manner, it appears that the form has influence upon the reception of food from the air; and Mr. Uflar believes, that the fituation of the leaves, the direction, circumference, margin, furface, promote the one or the other more or lefs: Folia *ferrata*, incifa *dentata*, acute *crenata*, &c. all thefe are not only better conductors, but alfo more capable of perfpiration, than fuch as have a fmooth or even margin.

Bodies armed with, or ending in fharp points, not only attract electricity better, but when impregnated with electric matter, they allow it to ftream out of them with greater velocity than fmooth or blunt bodies do; and as plants receive, not only elaftic fluids from the atmofphere, but alfo electric matter; it may be concluded from analogy, that their form will have likewife confiderable influence on this occafion.

The great difference among leaves, their different

ferent origin, and use, &c. is well demonstrated by Professor Batsch in his book, entitled, Anleitung zur Kentniss der Pflanzen, §. 87, to 102.

It appears from what has been obferved, that the aliment which the roots take up from the furrounding earth, fcarcely differs as to quality in different plants; and, that the alteration of it takes place only by peculiar co-operations and modifications within the particular plant: this is obvious in grafted fruit trees, and indeed in others; quercus *ilex*, for inftance, grafted or innoculated upon quercus *robur*, retains its leaves through the winter in a found flate like its mother plant.

That there is great variety of organization in plants, and that through various operations thence refulting, the various preparations are effected and produced, is very obvious; but of the manner, in which these are precisely formed and conducted, we have at prefent but an imperfect idea, yet fomething more fatisfactory, it may be hoped, fhall accrue from the indefatigable labour of chemists, mifts, who have already demonftrated, that the minute particles of two heterogeneous bodies, when intimately combined, poffefs a power to produce a mutual change upon one another; and have alfo found, that by the combination of different bodies, new bodies are produced, which are in all refpects the fame with those produced by nature.

Whether the external form of plants likewife originates from their internal condition and composition, like what we observe in unorganized bodies, as falts, &c.; is a subject, in our present state of knowledge, too early for discusfion.

Organized bodies poffels another power, already mentioned; which caufes their determined figure; *Nifus Formativus* of Dr. Blumenbach.

Mr. Uflar is of opinion, that the pollen of the flowers contains a very fubtile, elaftic, highly active matter, which gives the proper direction,

tion to the Nifus Formativus, under altered circumftances; this he concludes from the following obfervations.

1/t, Becaufe hybrid plants deviate always in their form from that of the female, and affume more nearly that of the male;

2*dly*, As a proof of the elafticity of this matter, it may be obferved, that the pollen, which is depofited, and which adheres to the vifcous humour of the fligma, cannot enter that organ, on account of the minutenefs of the pores, or mouths of veffels terminating on its furface. The impregnation muft therefore proceed indirectly, or mediately, by means of an elaftic fluid, which, being difengaged from the pollen, is attracted by the liquid of the fligma; and, in combination with this liquid, penetrates the fligma, and paffes to the germen; perhaps, there it acts as a flimulus, excites irritability, and thus produces alterations in the feed.

Irritability appears to be the principal effect; for, immediately after the deposition of the pollen, len, the embryo in the germen flows vitality or motion; the feed veffels open themfelves, fwell, and become filled with juices, which are gradually perfectionated in the germen.

There is fcarcely any doubt, that the accefs of air by this means, as well as in-general by the combination of the food with the folid parts, has here a confiderable effect. HALES fuppofes that it is probable, that the air contributes much to the concretion of the particles of bodies; and the fuppofition feems to be fupported by the obfervations of Mr. Achard, that the formation, cryftallifation, or confolidation of faline matters, is accelerated, and really occafioned by the combination of gaffes, fuch as fixed air, &c.

The pollen difcovers its elaftic and inflammable nature, alfo when blown into the flame of a candle; in which cafe, not only the particles which come into immediate contact with the flame, but all the reft are immediately kindled. One of the most important fubjects which can engage the attention of philosophical botanists, is the irritability of organized bodies. This was demonstrated with respect to animals, by the immortal Haller, and it is now more and more discovered to reside in plants.

Haller diftinguishes,

1/t, Nervous power (*fenfibilitas*), from 2*dly*, Muscular power (*irritabilitas*).

Befides thefe, we observe another in living bodies; that is,

3dly, Elasticity (elasticitas).

Very often are these three powers confounded, though they differ effentially from one another.

Elafticity is common to all parts, but in different degrees. This power was well known to Bellini, De Gorter, Stahl, &c. The latter called it the *tone* of the fibre; and derived from it the irritability; which opinion is, however, now found to be erroneous; as elafticity is a power different from all the reft.

That

II2

That it differs from irritability, is fufficiently demonstrated by Haller, Oeder, De Haen, Whytt, Zimmermann, Fontana, &c. vide Haller on Muscular Fibre, &c.; of which Mr. Uslar, the principal author of these fragments, has inferted, in the German original, a short extract.

The power of contraction of certain parts, exhibited after applied ftimulus, is alfo evidently obferved in plants, and is therefore not merely peculiar to animals.

Whatever deftroys the irritability in animals, does the fame in plants; as, for inftance, violent electrical ftrokes. Whatever excites irritability in animals, excites it alfo in plants. If the contraction obferved in dionæa *mufcipula*, mimofa *fenfitiva*, averrhoa *carambola*, onoclea *fenfibilis*, &c. be not confidered as effects of irritability, what caufe can be affigned for it ?

Other inftances have been given before, as, for inftance, in the vallifneria; and there is another in nigella *fativa*; at the time of impregna-

P

tion

tion of this plant, the antheræ and piftillum incline towards each other, and remain in the fame pofition until the impregnation be completed. Such motion cannot be called voluntary, as plants are confidered to be deftitute of volition; it muft therefore be of another kind, excited by an internal ftimulus. It cannot, asfar as we know, arife from the influence of nerves, as thefe have never yet been difcovered in plants. The principal modern authors who have written on this fubject, are *Ellis*, *Medicus*, *Girtanner*, *Gmelin*, *Hope*, *Percival*, *Cavallo*, *Sömmering*, *Wrifberg*, &c.

All fibres do not poffefs an equal degree of irritability; and hence, all the parts of organized bodies are not equally irritable. The caufe lies probably in the greater or leffer accefs of the principle of irritability, and in the various capacity of bodies for receiving it.

Those parts appear to be most irritable which are most frequently moved.

Mr.

Mr. Uflar has also convinced himfelf that plants poffess different degrees of irritability, without reference to their perceptible motion :

For inftance, refeda *odorata* is deftroyed by an electrical ftroke, which applied in the fame degree to another plant, lepidium *fativum*, does not hurt it in any degree.

The first is rendered fickly or gangrenous by water mixed with fuper-oxygenated muriatic acid, while the latter, when fuch water is applied to its roots, becomes more vigorous.

In the fpring, we often find that fome plants, as phafeolus *vutgaris*, &c. become gangrenous by the night's froft; while others, as pifum *fativum*, are never hurt by it; many other examples of this kind are obferved in garden and foreft trees, which prove the existence of different degrees of irritability in plants.

WE have farther to diffinguish :

1/t, Irritability, as the cause of many phenomena.

2dly,

2dly, The principle of irritability.

The first is understood to be the capacity of the irritable fibre to receive the principle, and its power of contraction.

The other fignifies the principle itfelf which animates the fibre, and without which this cannot exert its capacity or power by applied flimulus. From both these differs,

3dly, The flimulating irritating matter.

There is probably a very powerful penetrating principle difused throughout nature, and which affords the vital principle to all organized bodies.

Its exiftence was acknowledged at all times, as far as we know; but as to its nature, very different opinions have prevailed. Plato and Hippocrates already fuggefted their opinion on that fubject: The latter called the vital principle $\tau o iroquer$.

From the different degrees of irritability, which the fame body poffeffes at different times, that is, in the two conditions or flates in which the the irritable fibre may exift; namely, 1/t, When the principle of irritability is accumulated in it; and, 2*dly*, When exhaufted of it; it follows, that irritability depends on fome foreign matter or principle. Vide REHFELD, an Vis Irritabilis Fibrarum Mufcul. infita ipfis inhæreat, an aliunde ad eas accedat.

This principle appears very probably to be an elaftic fluid; and, according to Girtanner, it is the oxygen.

Oxygen is conveyed to all living bodies by the atmosphere and by their food; and their parts variously possess more or less capacity for receiving it.

If oxygen is the principle of irritability; it will follow, that its different proportion in the irritable fibre, must occasion different alterations.

If the irritable fibre contains the due proportion of it; then obtains,

1/l, The healthy flate, which Girtanner calls the tone of the fibre.

2.dly,

2*dly*, If the fibre abound too much with this principle, then the first preternatural state is caused, namely, that of ACCUMULATION.

3*dly*, If the mufcular fibre is defitute or deprived of it, then follows the ftate of EXHAUS-TION.

It has been before obferved, that living bodies receive the principle of irritability by their food and from the atmosphere. In order to prevent the accumulation of it, therefore, it is required, that fome matter be applied to them, which thall deprive the irritable parts of the fuperabundant portion; fuch fubftances or matter, are called STIMULANTIA, or ftimulating principles.

Now, if thefe are applied in a due proportion, corresponding to the increase of the principle, so that the fibres are deprived of the superabundant portion, and retain only that portion which is necessary for their natural state, then health is maintained.

IF

If on the contrary, the ftimulus applied, is disproportionate, then two cases are possible;

- a. If the ftimulus is too weak, then the fibres retain more than is neceffary, and accumulation follows.—But,
- b. If the ftimulus is too great, then the fibres lofe the principle more rapidly than they receive it from without; and exhauftion is the confequence.

Exhauftion may then be;

1/t, Temporary, or 2*dly*, Irreparable.

The first continues until the fibre has recovered the principle of irritability; and till that period, the fibre is infensible to every stimulus, or no stimulus can produce contraction in it.

But on the contrary, the exhaustion becomes irrecoverable, when the stimulus has been too great, e.g. in the cafe of a violent electric stroke, or application of strong poisons, so that the capacity of the fibre is destroyed, or the body is deprived of all its principle of irritability; then, gangrene

120

or decay is the confequence; the parts of the fibre become fubject to the laws of chemical decomposition, and putrefaction gradually follows.

Both, therefore, accumulation, and diminution or exhaustion, of that principle are difeases; the confequence of the latter we have just obferved; that of the first is the same.

By the accumulation, the fibres become too irritable; hence, the contractions they perform are more violent than they can fuftain. It is poffible, that the confequence fhall be, either that the fibre, by too violent action, fhall lofe its contractile power as far as this depends on the particular flructure; or, that the accefs of the principle fhall be cut off or interrupted by the loft capacity of the fibre for receiving it. In either cafe, a relaxation follows which leaves no hopes for recovery, for the weaker flimulus has the fame effect upon the fibre with accumulated irritability, as the flronger flimulus, e. g. electrical percuffion percuffion or poifon has upon that with the natural tone.

The effect of a froft in the fpring is thus explained; the greater the intenfity of cold, the more the principle of irritability is accumulated in the irritable fibre, becaufe the general flimulus heat is abfent, and becaufe, both for this and many other reafons, more oxygen combines with bodies that are capable of receiving it, in a lower than in a higher temperature. In fuch circumftances, the principle accumulates fo much in the fibres, that a fmall portion of fenfible heat is capable of inducing an irreparable exhauftion.

Two examples which prove this theory, were experienced almost throughout Germany.

1/t, In winter 1788-9, great deftruction was occafioned by the violent cold in forefts and fruit gardens, though fcarce any burfting of their veffels, from expansion of the water while freezing, was perceived in the trees, as there were no fudden changes of temperature.

Q

In

In the fpring, the greatest part of these trees produced flowers and leaves, which very soon thereafter, not only dried up, but the trees themselves actually died. The same was observed in those trees which were already in soliage, and had formed their fruits. This was the confequence of too great irritability; from which the fibres, by the application of the usual stimulus were greatly affected, and irreparably exhaufted.

2d, The month of April 1792 had already the appearance of June; in May, most plants were in bloom and in full foliage, and rich crops were expected: But by the frost which happened on the 7th and 8th of May, all these flattering hopes were destroyed.

On the 11th, Mr. Uflar collected the following obfervations:

a. The trees in the woods, on the east and fouth fide, having been most acted upon by the fun in the rifing of the day, had fuffered more by the frost, than those fituated towards the west

122

west and north. The leaves of most trees became gangrenous and decayed on the fide exposed to the fun.

b. All kinds of trees had not fuffered equally. The oak and beech had fuffered moft. Acer, fraxinus *excelfior*, betula *alnus*, had likewife fuffered much; but carpinus *betulus*, betula *alba*, forbus *aucuparia*, had fuffered much lefs, though. they all ftood mixed and interfperfed with the former. May not this be confidered to arife from their different degrees of irritability?

It is well known to gardeners, that when night frofts prevail in the fpring, it is neceffary to protect the tender and most irritable plants with matts, and thus defend them, not only against the cold, but also against the fudden effects of the fun, and heat thereby induced.

The covering appears to prevent the accumulation of the principle of irritability in the fibre during the night; and also the too violent effects which would then be caused, by the stimulus of light and heat.

The

The increasing temperature, as the day-light increases, affords already a fufficient stimulus for them; plants are thus deprived of part of their irritability, which in due proportion, gives tone to the fibres, and by this they become gradually capable of fustaining the stimulus induced upon them in the middle of the day without injury.

The change of the fibre from the accumulated flate to the moderate, and from this to the exhaufted flate, proceeds very quickly. Such changes, we obferve in the phenomenon which is called the Sleep of plants. But the irritable fibre when exhaufted, recovers its irritability very flowly.

According to Mr. Uflar's opinion, a plant, particularly an evergreen; as Ilex *aquifolium*, or quercus *ilex*, whofe initability has increafed during the winter; if in the approaching fpring, it were placed and well preferved in an icehoufe, would become fo very irritable, that when afterwards taken out and fuddenly expofed fed to the warm atmosphere of the fummer, it would be fo exhausted in a short time, that the capacity of its fibres would be entirely destroyed.

THE irritable fibres of organized bodies have a connection or fympathy with each other (confenfus), from which follows;

Ift, That a ftimulus applied to one is communicated to the reft: But the effect of the ftimulus thus applied to the fibres, is in general greater upon that which first receives it, and proportionally lefs upon the others as they are more remote.

If a branch of the mimofa *pudica* be touched, it fhrinks and collapfes; the ftimulus which is produced by the touching, produces an effect upon the whole plant, but not equally upon all its parts.

2*dly*, If the ftimulus applied to one fibre has an influence upon the reft; it follows, that if the one is injured in any way, it must then likewife affect

affect the other; that is, if one fibre be deprived of its principle of irritability, then the fame change will take place in the other connected fibres, but in a lefs degree.

- a. Becaufe the flimulus applied to one fingle fibre, affects the whole fystem of fibres, and every flimulus occasions a loss of a part of the principle of irritability.
- Becaufe the reft of the fibres afford fupply to the exhausted fibre, by parting with fome of their own principle, provided this fingle exhausted fibre has not lost its capacity for receiving it.

The more frequent the filmulus is applied, the more the fibre is deprived of its principle of irritability, the lefs irritable it becomes, the lefs is the effect of the filmulus, and the contraction is diminithed in proportion; if the fibre is quite exhausted, then the effect of the filmulus ceases totally. This is one of the most interesting facts which Girtanner has demonstrated, monftrated, and which shall be more confidered in treating of the fleep of plants.

The degrees of contractibility is in proportion ; to,

1/t, The degree of irritability which the fibre poffeffes;

2dly, The intenfity of the ftimulus.

As there exift different degrees of irritability and ftimuli of different power.

Bodies when difpofed to come in contact with the irritable fibres, exert different effects upon them, according to the degree of attraction of the oxygen for them.

If the attraction of oxygen is greater for the foreign body than for the fibre; in this cafe the body takes the oxygen from the fibre, and the fibre lofes thereby its irritability; all bodies of this nature are called Stimulating Subftances.

But, if on the contrary, the oxygen has a greater attraction for the fibre than for the body which is brought into contact with the fibre, then

then the body lofes its oxygen, which the irritable fibre takes up, and thence its irritability increases.

If the attraction for oxygen is equal in both, then no alteration takes place, and bodies of this kind do not increase nor diminish the irritability.

To the flimulating matters, belong : heat, light, electric matter, fpirit of wine, carbonic acid gas, and all gaffes which have a ftrong attraction for oxygen, viz. hydrogen gas, &c.

Leaves immerfed in water impregnated with carbonic acid, foon lofe their irritability and fade. All bodies which contain oxygen, and which, when brought into contact with the irritable fibre, lofe their oxygen by a fuperior attraction of the irritable fibre for this principle, Increase the irritability of the fibre; viz. fuperoxygenated muriatic acid, metallic oxyds, water, as this latter is decomposed by plants; cold, in fo far as by a diminution of fensible heat, one principal flimulus is leffened, fo that the fibre being

128

lefs irritated, retains the oxygen from the decomposed water, whence the irritability of the fibre is increased. A fimilar effect of the accumulation of oxygen by cold, is observed in the manufacturing of paper; for paper made in the winter by a strong cold, is much whiter than that which is made in the fummer.

Heat as a ftimulus excites the activity of the veffels, and promotes vegetation in general; the living power is confidered as an alternate contraction and extension of the fibres. Cicero already confidered heat as the vital principle : " Omne vivum, five animal, five terræ " editum, vivit propter inclusum in eo calo-" rem."

Asto the effect of the matter of heat, we know, that if it is applied as a ftimulus to plants, proportionably to the irritability of the irritable fibre, it then promotes vegetation: But if the heat is proportionably greater than what the fibre can fuftain, in fuch cafe, an irreparable exhauftion and death will follow.

Heat always caufes a diminution of the irritability of the irritable fibre, and this is neceffary to prevent accumulation. MEDICUS has found, that the irritability of plants is greater in the morning, lefs in the middle of the day, and much lefs in the evening. Mr. Uflar was well convinced of thefe facts by his obfervations refpecting the fleep of plants; he alfo found, that by long continued rainy weather and cool air, the irritability of thofe plants, whofe irritability is obfervable by contractions, was confiderably increafed. The proofs of the effects of a moderate heat promoting vegetation are numerous, and very obvious in hot-houfes, &c.

Many animals which hide themfelves during the winter, and remain apparently lifelefs in their cells, difappear, as Mr. Spallanzani has obferved on the lacerta *falamandra*, at a feafon when the temperature of the atmosphere is much higher than in the fpring when they again make their appearance. The caufe of this phenomenon lies in the ftate of irritability; in the autumn, the fibre fibre is much exhausted by the heat and light of the fummer; but, in the approaching spring, the irritable fibre is in the accumulated state, by the greater absence of those principles during the winter; in which case, a less degree of heat has a greater effect, than a higher temperature could produce in the autumn.

This explanation may with much propriety be applied to fimilar phenomena obfervable in vegetables, and many other phenomena may be explained upon the fame principles.

Vigorous is the growth of plants in the fpring, quick the motion of their juices, and from month to month both decreafe: By the approach of the autumn, vegetation is ftopt, and in the fineft days of the autumn, at which time it is even warmer than in the fpring when plants grow fo vigoroufly, the vegetable tribe is fo abforpt in fleep, that the light of the fun is then not capable to awaken them. The warmer the fummer had been, and the more the fun had fhone, the fooner the leaves of trees and plants change their

their colour; and the longer they retain their green colour, if the fummer has been cool and the fky much covered with clouds.

Plants which have flood all the winter through in warm rooms, grow but flowly in the fpring when other plants grow very vigoroufly. In order to preferve the plants growing in rooms, it is very proper to expose them occasionally to a colder atmosphere. Mr. Uflar recommended this, and the refults of experiments were always agreeable to his theory of irritability; it however must be done with caution, and the plants must not be too long exposed to a cold air, nor in a very cold atmosphere, elfe the principle of irritability accumulates too much, and the warmth of the room becomes then too great a fiimulus, and injures the plants. This is not the only remedy for procuring • new ftrength to plants that grow in rooms, but any fubftance which fupplies them with oxygen answers the purpose ; as, for instance, moiftening the earth in which they grow, with water

water containing a little fuper-oxygenated muriatic acid; of which more will be mentioned in the following part.

Respecting the different degrees of irritability in different plants, Mr. Uflar had made many obfervations.

Plants from warm climates, he found generally more active than those from more northern. Jasminum *azoricum* still produced branches and leaves, when plants of a colder climate had long ceased to grow.

It appears to M. Uflar, that the plants of northern climates, are more irritable than those of the warmer climates; and although organized bodies, by change of climate, change in fome respect their constitution in the following generation, yet we find that they retain always fome difference respecting their irritability.

Moft of the plants which have been tranfplanted from their warmer climates into our northern, part, for inftance, later with their leaves, and likewife change their colour later, and not unlikewife

frequently we find the wood of a paler co. lour.

So, for inflance, the wood of trees which grow nearly under the equator, is of a deeper colour, viz. fwietenia mahagoni, cæfalpinia brafilienfis, hæmatoxylum campechianum, afphalathus ebenus, \mathfrak{Sc} . This is not merely limited to the wood, it is alfo obfervable in the green colour of the leaves. The leaves of trees of hot climates are generally of a deep green colour, viz. cafuarina equifetifolia, or at leaft they are of a deeper green than those of the plants of northern climates.

Moreover, it is known, that the colour of animals living within the tropics, is not only deeper and more fhining than of those which live nearer to the poles, but that they also change their colour into a paler one when they are. transported from thence into our northern countries.

The caufe of the paler colour appears to be the prefence of oxygen, a fuppofition which is verified

verified by the obfervation, that all vegetable fubflances which cannot part with oxygen are colourlefs.

This is fhown by nature, and proved by experiments. If plants are placed in the dark, where they muft retain the oxygen which they receive, they become paler and more irritable. Branches, or wood, which cannot abforb it are white; plants which do not emit pure air, or only a very fmall portion of it, viz. Fungi; lichen parientinus, L. pallefcens, L. lacteus, L. ericetorum, L. miniatus; melampyrum nemorofum, &c. are almost colourlefs: but all the parts of plants, as leaves and calyx, and all plants which yield pure air, are coloured.

That oxygen is the principle of irritability, will be more fully proved by experiments. Plants acquire oxygen from their aliments, and from the air : they receive it by decomposing the water. Plants take a certain portion of it combined with hydrogen and carbonaceous matter into their conflitution : they part with fome of the received

received oxygen again by the applied flimulus; and it appears that the deeper the colour is of plants or their parts, the lefs oxygen do they take up, and the more carbonaccous matter do they contain.

If oxygen be the principle of irritability, it will follow :

1/l, That plants of a deep colour are more irritable than those of a lighter colour : and from the deeper colour of plants of hot climates, we may conclude :

2*dly*, That thefe are lefs irritable than plants of northern climates.

That fuch difference of irritability in plants exifts, appears very evidently; for, if the plants of hot climates were not lefs irritable, the continual uninterrupted growth of plants within the tropics would be impoffible : they would be exhaufted like those of our countries, and they could not fustain the ftronger ftimulus of light and heat : we may hence perceive, why barley ripens in Lapland in 60 days, and why

ON PLANTS.

why it requires twice that time in France. The explanations now offered of the different abovementioned phenomena, are derived from the principles of the new theory; and deferve highly the attention of philosophers.

MR. GIRTANNER draws fome general conclufions from the doctrine of irritability, fuch are the following :

The irritability of living bodies always bears proportion to the quantity of oxygen which they contain; hence it may be deduced,

1st, That whatever increases the quantity of oxygen in organized bodies, increases also their irritability.

2*dly*, Whatever diminishes the quantity of oxygen in living bodies, diminishes at the same time their irritability.

The following experiments which corroborate what has been just mentioned, were made in fupport of Mr. Girtanner's principles by Mr.

S

Uflar, .

Uflar, and they are confirmed by the obfervations of Mr. Von Humbold in his Flora Friburgenfis Subterranea; Mr. Uflar took different feeds and plants, and caufed an accumulation of oxygen in fome, while no fuch accumulation took place in the reft: he found, that under certain circumflances, the firft germinated fooner and grew quicker than the latter. In order to difpofe plants for imbibing more oxygen, it is neceffary to apply to them bodies, which contain the oxygen but weakly combined, or from which it is eafily feparable, and whofe bafis has lefs attraction to oxygen than the vegetable matter has; fuch a body is the fuper-oxygenated muriatic acid.

Mr. Uflar fowed lepidium *fativum* in two different pots, the earth of the one he moiftened with pure river water, and that of the other with the fame kind of water mixed with fuper-oxygenated muriatic acid. The feeds in the latter germinated much fooner than in the former, which

was

I38

was only moiftened with pure water, and which confequently could not communicate to the plants fo much oxygen as the other, and thence too, the plants in it were much retarded in their growth. In thefe experiments it is to be obferved,

ift, That the quantity of fuper-oxygenated muriatic acid which is added to the water muft not be too great; otherwife, it proves rather noxious than beneficial, as the oxygen accumulates, the plant becomes too irritable, and bad confequences foon follow.

2*dly*, That the germinating plants, efpecially thofe which are impregnated with oxygen, are not to be immediately exposed to the fun rays; for light proves generally hurtful to the embryos and germinating plants, or while in their earlieft ftage; the caufe of it is the too great irritability at this period, which however diminishes with the increasing age of the plant.

Those feeds which were moistened with an equal quantity of super-oxygenated muriatic acid and water; and of which some were expofed fed to the fun, others kept in the dark exhibited very different phenomena; the first did germinate, but their colour foon changed; they became gangrenous and faded.

The latter germinated likewife, but they were left covered until the first leaf was evolved, and were not till then placed in the light: these made a rapid growth, and soon reached their state of perfection.

Befides what is above-mentioned, there is an, other chemical caufe, whence the bad effect from expofing plants fuddenly to the light, may be derived; namely, it has been obferved, that light has a ftrong attraction for oxygen. It is this which renders the formation of fuper-oxygenated muriatic acid fo difficult, and which caufes the feparation of oxygen from this acid when expofed to the light of the fun, fo that the muriatic acid is then left behind in its common flate. Mr Uflar convinced himfelf by experiments, that the common muriatic acid has a very different effect from the fuper-oxygenated muriatic tic acid, very probably by reafon of the weaker attraction of the oxygen in the latter acid.

The refults from the experiments made with other feeds; as, for inftance, with braffica *campeftris*, braffica *napus*, lactuca *fativa*, pifum *fativum*, refeda *odorata*, coincided with the refults of the experiments before mentioned.

In order to afcertain in a more fatisfactory manner, that the greater proportion of oxygen caufed the vigorous and quick growth of plants, Mr. Uflar varied his experiments.

ift, He took pounded quartz inftead of earth, and moiftened one portion of it with the fuperoxygenated acid, another portion with pure water; the refult was the fame as in the former trials.

2d, He took a metallic oxyd, namely, oxyd of lead or litharge, and he found that the plants grew very well in it, and better indeed than in pure earth. This proves befides, that all metallic oxyds do not deftroy plants.

Mr.

142

Mr. Uflar alfo made the following experiments, in confirmation of the hypothesis, that oxygen is the principle of irritability.

He moiftened, with fuper-oxygenated muriatic acid, earth in which he had planted mimofa pudica, and drofera rotundifolia, and he thereby brought them, not only to the higheft degree of irritability, but he found that if he continued the accumulation, the light had fo great an effect upon them, that they were deftroyed by that ftimulus. Other plants which fhowed fcarce any marks of irritability, foon became irritable; all loft their irritability, often to irreparable exhaustion, when too often and too. long fiimulated, and when the fupply of irritability was cut off.

The different degrees of capacity of different plants were also observable, as some took up so much oxygen from the fame impregnated water, that they loft their proper colour and died; while others of different species, continued to grow vigoroufly.

It

It appears that the durability of organized bodies, particularly of plants, bears a certain proportion to the time in which they come to their perfection.

Forresters have frequent occasion to observe, that not only trees which grow very fast are of fhorter duration, than those which require a longer time to come to their perfection; e.g. falix, betula, populus; compared with quercus, fagus, acer; but alfo, that those whose growth has been accidentally accelerated, feldom arrive at the ufual age which nature had determined for the fpecies to which they belong. Not unfrequently we find, that trees ficken when growing in too rich foil. Of this Mr. Uflar was fatisfied by experiment: by the increased supply of oxygen, and by plenty of food, the irritability is increased, and confequently the growth haftened: but he alfo found, that plants thus hurried on to bloffoming and perfection, were not of fuch durability as those which arrive at those states in the natural course of time.

Pure

Pure air (oxygen gas) is in general favourable to vegetation, and even neceffary to it; but azotic gas, and hydrogen gas, when plants are included in them, prove fatal to them. Yet there are exceptions as to both, not only in certain circumftances which fhall be mentioned on another occafion; but alfo according to the various conftitution of different plants.

Some plants grow better in bad air than in an air which contains much oxygen: Plants growing in deep mines are examples of this; for if fome of them are removed and exposed to atmospheric air, they foon die; many of the byffi, lichenes, agarici, &c. grow not only in azotic or hydrogen gas, but even better than they do in the common atmospheric air, and they will not grow at all in pure air. The cause of this appears to be the want of a fufficient portion of hydrogen for their proper composition, and also the great irritability of their fibres, while the principle of irritability is not proportionably accumulated to fufficient the fimulus.

The

The vital power of plants was formerly fuppofed to be derived from the alcent and defcent of the juices, and this motion again, from the attractive power of the veffels for the nutritious juice; juft as fluids rife in capillary tubes, from the attraction of the glafs for the fluid: in like manner, a number of capillary tubes were imagined to exift in plants, extending from the roots to the extremities of the branches, and in which the juice rofe upon the fame principle as in capillary glafs tubes.

This explanation Mr. Uflar contends to be repugnant to found phyfiology, and he thinks that it is impoffible that by this power alone, the juice can be conveyed to the extreme points of high trees.

Hales confidered the afcent of the fap as the effect of heat and air, by which the juices were attenuated and more difpofed for afcending, but this hypothefis appears very unfatisfactory. The doctrine of irritability leads to another theory, which is fupported by many facts.

Withour,

Without internal activity and contractility of the fibres, the quick circulation of the juice in many plants could not take place: were this effected by heat, it must be expected that the circulation should be quicker in the fummer than in the spring; but we find, that the circulation of the spring in plants is quickess and most copious in the spring, when the plants are most irritable.

Mr. Von Marum has now decided this point in a differtation, *De Motu Fluidorum in Plantis*. Groningen, 1773; towards the end of it he fays:

" Videtur verifimillimum, ipfis plantarum va" fis actionem quandam effe attribuendam, quæ
" abforptos humores profundat verfus illam par" tem, quæ minorem offert refiftentiam; quæ" nam autem fit illa actio, inquirendum ref" tat.

" Diametro alternatim diminui aut augeri " plantarum vafa, et hac ratione contentos hu-" mores ⁴⁴ mores urgeri, ex una vaforum parte verfus al-⁴⁵ teram, requiri videtur.

" Utrum vero hæc vaforum conftrictio oria. " tur a vi quâdam contractili ipfis infitâ, quæ " a contractilitate vaforum animalium non di-" verfa eft, an vero ab aliâ quâdam vaforum fa-" cultate derivanda, haud facile determinare li-" cebit."

It appears probable, that the veffels of plants poffers a contractile power, fuch as Haller called irritability in animals. And it has been demonftrated by many experiments, that the diminution and extension of the diameter of the veffels, is produced by means of the fpiral and circular fibres.

When Mr. Marum obferved that milky juice flowed from the end of a branch of euphorbia when frefh cut, he immediately endeavoured to enquire into the caufe of this phenomenon; and he compared it to that caufe, to which the bleeding must be afcribed, when fmall veins of animals are cut afunder, *viz.* the alternate contraction

traction and dilatation of the veffels, during the circulation of the blood in animals.

Irritability is the caufe of contraction; if the contraction in the veffels of plants arifes from it, it will follow that their action will ceafe as foon as the irritability of the fibres is deftroyed : and if fuch fhall be found to be the cafe, it may be deduced ;

1,*A*, That contraction caules the flowing of the juice from the veffels.

2*dly*, That the caufe of the contraction must be derived from the irritability.

3dly, That this, and its effect contractility, must cause the circulation of the juices.

In order to be convinced of the affertion, that ftrong electric flocks kill animals, by depriving them of, or deftroying the irritability of their irritable fibres, Mr. Marum for want of amphibious animals, which retain fome of their irritability for a confiderable time after they are killed, took eels (muræna anguilla), which, as is known, poffefs the fame power. By means of the

the Teylerian electric machine, he paffed fhocks through feveral of thefe animals, and the refults of his experiments were;

1/t, When the ftream of electric matter pervaded the whole animal from head to tail, it died immediately, and no mark of irritability could be difcovered, even in its fmalleft parts, by any ftimulus whatever.

2*dly*, But if the ftream was directed through certain parts of the animal only, then he found that those parts only had lost their irritability, and consequently their contractile power.

These experiments, tried upon animals with warm blood, succeeded of course equally, as the irritability of their muscular fibre does not remain so long after death.

These experiments fufficiently proved, that the irritability of animals was fuspended by the electric shocks; in order to ascertain the same with respect to plants, he took various species of euphorbia, viz. euphorbia campestris, (perhaps escuperation of the state of the state

and fent a ftream of electric matter through them; he then cut off the ftem, but no mark of effusion of the juice was now observed; the fame was remarked in ficus *carica*.

If the ftems of thefe were afterwards fqueezed with the fingers, then fome juice was forced out as long as the preffure was continued, which afforded a proof, that a certain power which had caufed the effusion in former trials was now deftroyed (namely irritability.)

By fending a ftream of electricity through fingle ftalks of thefe plants, the refult corresponded with the experiments upon certain portions of animals, as in this cafe, only the particular part which had fustained the flock had loft its irritability.

It is not electricity alone which produces this effect in plaints; there are other ftimuli which may effectuate the total exhaustion of irritability, on which the contraction of the spiral and circular fibre depends. Mr. Uslar succeeded at different

different times in experiments with euphorbia peplus, and efula, whofe irritability he had highly accumulated, by increafing the fupply of oxygen, and by removing the habitual flimuli of heat and light, fo that when he expofed them afterwards fuddenly to the light of the fun when in the zenith, they became gangrenous and dry in a flort time. Mr. Uflar cut off from time to time, the flalks as they approached to this flate; and he found, that although the efflux of the juice did not totally ceafe before they died, yet it was confiderably diminifhed, in comparifon with what was obferved in other plants of the fame kind which had their proper tone.

From what has been observed on this subject, it follows:

1/l, That the contraction of the vegetable fibre is owing to irritability, as well as that of the animal fibre, and that both are fubject to the fame laws.

adly, As the caufe of the circulation of blood

3

in

152

in the animal body, is derived from the irritability and contraction of the fibres and veffels, we may fuppofe with fome propriety, that the circulation of the juices in vegetables, may be effected by fimilar means.

ANOTHER remarkable phenomenon which is probably connected with irritability, is the fleep of plants.

The animal body requires reft, *i. e.* fleep; this is the ftate, during which the fibres and organs recover new powers for future activity, which they had loft by their frequent exertions.

The flate of plants which is called the fleep of leaves, or more generally, of plants, appears to Mr. Uflar to be fimilar to the fleep of animals; and though we do not perceive it by external marks in all plants, it does not thence follow, that fuch do not enjoy it, or that their fibres do not become exhaufted, nor require any time for reft.

There

There are but few plants, in comparison to the great number of plants produced, that show irritability by visible contractions, and yet all plants are more or less irritable. If we confider the cause of the sleep of plants, it will appear the more probable, that this phenomenon does exist in all plants.

Long before Linné, it was obferved that plants enjoyed reft at certain times. Garzias obferved this first in tamarindus *indica*; afterwards Dr. R. Camerarius wrote a differtation, De Herba Mimofa l. fentiente, in which the fubject was more fully treated; at last appeared the great Linné; his attention to that fubject, was particularly engaged by the lotus *ornithopodioides*; he then demonstrated the fleep of plants, directly by obfervations and experiments, and shewed that it naturally took place in plants, fucceeded regularly, and was independant of any extraordinary accidents.

With refpect to the fleep of plants, he also observed many circumstances analogous to that

U

of

of animals, e. g. that young plants like young animals, fleep longer than those fully grown up. The cause feems to lie in the different degrees of irritability in different ages.

Sleep is reft, the time when fibres and organs recover from their relaxed or exhausted state, which has been induced by the living activity or irritability.

The whole organization is not deprived of activity by fleep, for the uninterrupted motion does not ftop; this only takes place after death.

Animals and plants generally choofe the night for their reft, becaufe two habitual flimuli, light and heat, are then either altogether or moftly abfent.

Plants which are only active in the night, are perhaps too irritable, and animals which are awake in the night, are not unfrequently forced to it by fear, and the particular economy of their life.

The fleep of man, confifts principally in reft of

of the nerves of the brain; the more perfect this is, the more completely are fulpended fenfation and concioufnefs, and with the geater power do men awake again for new activity. If the fibres of their body be too irritable, if the fitimulus, for inftance, of heat, aliment, fpirituous fubftances, are not fufficiently withdrawn, then the mulcular fibre thereby ftimulated, acts upon the ambient nervous fibre, the imprefion is communicated to the brain, and the fleep is lefs quiet, and lefs found.

The greater the previous exertions of the animal body have been, and the more irritable it was, the greater is the relaxation.

Motion is a mechanical ftimulus upon the ir ritable fibre: Mr. Sauffure obferved, that a moderate motion which he made on the fummit of Mount Blanc, fatigued him more than a confiderable one on flat land; cold, or perhaps pure air on the mountain made the fibre too irritable, and the motion as a ftimulus, was out of proportion to the irritability.

The

The fame laws are obferved in plants. The more they are excluded from heat and light during the night, the more perfect is their fleep; the more irritable they are, the fooner they are exhaustable, and the greater the flimulus is, and the longer it is continued, the more they are exhausted.

By means of a continual flimulus, the perceptible irritability of a mimofa may be abolifhed or fufpended. All this leads to the analogical conclusion, that plants may be relaxed like animals, and that both require a time in which they may collect new powers, (*i. e.* accumulated principle of irritability), in order to become fit again for further exertion.

The congregation of nerves in animals exifts particularly in the brain, every flimulus induced upon the irritable fibre, is communicated through this to the others, by acting upon the annexed nervous fibre, whereby animals perceive impreffions upon the fenfes; by removing the flimulus, and by the exhaustion of the irritable

ritable fibre, concioufnefs and a certain degree of fenfation are fufpended, the nerves receive no impreffions; and if their fibres, like the reft of the animal body, are capable of relaxation, they then have time to recover their powers.

Abfence of ftimulus, and diminution of irritability, are therefore the caule of fleep; and abolifhed fenfation, or a diminution of fenfation, are merely the confequence of those caules.

We cannot therefore fay, that all organized bodies, in which we do not perceive evident marks of fenfation or concioufnefs, muft be alfo incapable of fleep, the conclusion would be as inconfequential, as if we were to affert, that all animals which are defitute of brains, are alfo incapable of fleep; or that those beings were deflitute of fenfation, because in animals which have a brain, fensation depends particularly upon that organ. Have not infects fensation, though they have only nodes of nerves instead of a brain? Do we not perceive fensation in worms, in which no nerves have yet been difcovered? vered? And do not all thefe beings fleep? Many obfervations might be produced in confirmation of this fuggestion.

Mr. Uflar after having made many obfervations refpecting the marks of fleep in infects; draws the following conclusions, that all bodies which poffers irritability require fleep, *i. e.* that periodical reft is neceffary for them, during which they recover from their exhausted flate, and collect new irritability.

Many experiments which fhew that plants by too frequent, long continued, and violent ftimulus, become exhausted and relaxed, led him to this conclusion, that the uncommon position which we perceive at certain times of one or other parts of plants, is really a state of rest, and fimilar to the sleep of animals.

That during this time the growth is not ftopped, cannot be proposed as an objection, because animals grow likewise during fleep; their power of reproduction proceeds, so does their respiration and digestion.

We

We find that different animals fall into particular poftures when afleep, and that fome do not flow any external marks of fleep; and that there is great diverfity as to the time and the duration of fleep in different animals: we find fimilar varieties in plants.

Some plants fleep in the night time only, others fleep alfo during certain hours in the day, fome difcover the flate of reft clearly by their external appearance, and others again, manifeft very flight or fcarcely any marks of fleep; folanum nigrum, ranunculus repens, &c. flut their flowers fome hours in the day, fpiræa *filipendula*, &c. is flut in the middle of the day, cactus grandiflorus, opens the flower only at the fun-fet, and fluts it in the morning, mefembryanthemum noctiflorum, awakes likewife only in the night.

Some plants when at reft, join the upper fides of their leaves, viz. alfine media, others fix them on the stalks, like cenothera mollis, &c. In fome, the leaves become erect, in others they droop or fall down.

Linné

Linné has mentioned all these various dispofitions of the leaves, in his Philosophia Botanica, and in the Amœn. Acad. IV. §. 340. et seq.

It was obferved, that the clofing and opening of the leaves and flowers of certain plants, varies according to the weather and condition of the air; fuch were called FLORES METEORICI: others which varied according to the length and fhortnefs of the day, and which flut at fun-fet, were called ÆQUINOCTIALES; and those which did fo at certain hours in the day, were denominated TROPICI. From observations of the last kinds, Linné formed the horologium *floræ*.

Several authors who have written on this fubject, attribute the general caufe of it to light and humidity. Mr Uflar agrees with them, and allows both; but he takes the whole in rather a different fenfe, and adds, that whatever acts as a ftimulus to the irritable fibre, may contribute to the effect; therefore, not only light and humidity, but alfo heat and alteration in the ftate

ftate of the atmosphere; as, for inftance, the degree of electricity, the admixture of carbonic acid gas, have influence upon the fleep or reft of plants.

We know the effect of electricity upon the irritable fibre of the organized body, and the influence of it upon vegetation in general will be afterwards demonstrated; we shall here only obferve, that most plants which difcover strong marks of fleep by their external form, have pinnated leaves (folia pinnata.)

Light, heat, hydrogen gas, are matters which act as ftimuli upon the irritable fibre; if the fibre is too irritable, then exhauftion and the ftate of reft follows.

Without light, or in abfence of it, without hydrogen gas, plants cannot continue nor perfect their growth; proofs of this we obferve in plants placed in atmospheric air excluded from light, and in those which are also excluded from light, but furrounded by hydrogen gas;

X

for

for instance, plants which grow in deep mines, filled with bad air.

Both these act as flimuli, and deprive the plants of the surplus of oxygen, that is, of the accumulated irritability.

If the flimulus is too great, too frequently applied, or too long continued, then exhaustion follows, the fibre is of courfe relaxed; this is obfervable in many, partly by the interrupted external motion, partly by the marks of fleep.

Heated air, and the heat of the fun relax animals and plants; hedifarum gyrans, we find, ceafes to move in the middle of the warmeft days, particularly if by previous circumftances, e. g. low temperature, or moifture, the irritability of the fibre had become accumulated.

Mr. Uflar found the fame refults in experiments with the mimofa, if the irritability had been increafed; he obferved that the leaves and ftalks collapfed fooner than ufual, according as the fun had fhone fhorter or longer upon them, and

and by no other means was he able to awaken them from their fleep, than by applying fuch a body as could afford a frefh fupply of oxygen.

If we only look into gardens, forefts, meadows, we perceive that plants which have been relaxed and deprived of moft of their irritability by heat, are quickly recovered by rain; for in this cafe the water affords the oxygen, and agreeably to our new theory, replaces the loft irritability.

Plants in their natural flate all follow those laws, which have been already noticed. Most awake at the rising of the fun, and return again to a flate of rest at fun-set.

In fhort, plants are found to be more irritable and more active in the morning; exhausted, less irritable, less active in the evening; and it appears that diminished irritability is the cause of the phenomenon called the fleep of plants; be it in the middle of the day, or in the evening, early or late in the day, the cause lies always in the ftate

ftate of the irritable fibre; all are fubject to exhauftion and relaxation, and all require a time wherein they may recover new ftrength. Thus Linné De Somno Plantarum: "ut quiete "tranquillâ fruentes novas quafi vires recupe-"rent."

Suppose the flimulus which causes the relaxation is not removed; is it notwithftanding poffible that plants can fall into a flate of reft? Why not? the ftimulating matter is only active as the fibre poffeffes irritability. It is therefore, not against the principles of our theory that the portulaca oleracea, fpirea filipendula, &c. fhould fhut in the middle of the day; and although the latter awakes only in the morning towards nine, yet the caufe why its fibres fuffer a temporary exhaustion in the day, lies in their greater irritability : this may be faid of all those plants which cease to be active in the afternoon about four or five; and the reafon why thefe require a longer time for recovery, depends

pends on the peculiar capacities of the fibres to regain the oxygen of which they had been deprived.

The more irritable animals and plants are, the more readily and the fooner they become relaxed, and the more frequently they require reparation : If, therefore, portulaca *oleracea*, folds up fo early as 11, the caufe is to be fought for;

1/t, In the fpecifically greater degree of irritability of the fibres:

2*dly*, In the greater irritability which it poffeffes in the morning.

Its irritability is at this time too great, and therefore not in proportion to the ftimulus; the fibre is exhausted: and the ftimulus becomes only active again, when the principle of irritability has been again accumulated, and this takes place only as far as these ftand in a more equal proportion with each other.

Many other phenomena may be explained upon the fame principles. But it may be afked, if exhauftion of the irritable fibre is the caufe

of

OESERVATIONS

166

of the fleep of plants; how does it happen that the fibre is not irreparably exhausted when the ftimulus is not removed? To this Mr. Uflar replies, that when an irreparable exhauftion does take place, an uncommonly great accumulation, caufed e. g. by a great or intenfe cold, muft have previoufly exifted; and in this cafe, the ftimulus acts not as being too long continued. but as being unproportionable and too violent. hence it deftroys the capacity of the fibre. As long as the fibre retains the capacity to receive irritability anew, the exhaustion is only temporary; but if plants are deprived of that disposition by which they receive the principle of irritability, then the temporary exhauftion is changed into an irreparable one; this we obferve to happen by a too long continued heat and drouth, and by a dry electric atmosphere : if the plants are only relaxed, and not totally exhausted by the greatest degree of stimulus, and if they stand in connexion with bodies from which they can receive a fresh supply of the principle of irritabili-

3

ty,

ty, then the effect of the flimulus is only fufpended, and only until the fibre is become irritable again.

HILL fays in his differtation on the Sleep of Plants:

" When he made the light fall upon plants 66 in different degrees, he found that their fleep was accordingly more or lefs perfect. Or that 66 the more intense the light is which falls up-" on plants, the more is their irritability, their " principle of life fet in activity; and the lefs " the ftimulus is in proportion to their irritabili-" ty, the greater degree of irritability remains " in the fibres, and the more fenfible they re-" 65 main.

He fays farther :

" According to the degree of light he had " applied, was likewife the degree of fleep." *i. e.* the greater or lefs the degree of flimulus to a certain point has been communicated, the more

OBSERVATIONS

more or lefs the fibre is exhaufted and relaxed, as on this depends the degree of fleep.

In animals we obferve the fame, their fleep is more found when they have been more ftimulated; but too violent ftimulus occafions a revolution in their body which approaches to difeafe, and from which they flowly recover, fooner, however, or later according to circumftances.

If we will not acknowledge the irritability of plants, if we do not admit, that the fun's light acts as a ftimulus, and that by it the irritable fibre can be exhausted; it then must appear a mystery, why plants should show indication of taking reft at the time when the fun is in the zenith, while it is allowed by botanist, that the fun's light animates vegetables. But should not the following facts be deemed a proof of the irritability of plants, its exhaustion and accumulation ? *viz.* that all the phenomena already mentioned, can be produced by other stimuli besides light, *e. g.* hydrogen gas, and carbonic acid gas; for the effects of these upon plants are stimular to those

168

thofe of light; the plants undergoing fimilar changes in perfect darknefs, when exposed to them, as by the application of light.

PLANTS, as we know, have different kinds of irritable fibres, ftraight, circular, and fpiral; a ftimulus applied to them occasions contractions, which appear according to the nature of the fibre by decurtation of the fibre, by diminution of diameter, or peristaltic motion.

HEDWIG afferts, that the origin and formation of the leaves and flowers are effected by the fpiral veffels: when, therefore, a ftimulus acts upon the fibre, a contraction enfues, and plants are forced mechanically to give the leaves and flowers a certain direction, and thus contract particular parts or extend them.

If the vegetable fibre is deprived of its irritability, it flags, the ftraight fibre is then elongated, the others extend their diameter, and thus naturally follow different positions of the ftalks and leaves.

Y

OBSERVATIONS

In this manner, Mr. Uflar imagines the opening of the flower is effected; if light, a moderate heat, or other ftimulus acts upon the fibres and veffels of the calyx and petals, they contract, and the flower opens, to which certainly the life of the whole plant affifts. The periodical clofing of many flowers may likewife be explained by the extension of the contractile fibres and veffels.

Mr. Uflar has convinced himfelf by many experiments, of the juftnefs of Dr Ingenhouz's obfervations, that many plants would furely die in hot weather in a few days if they had not time during the night for reft. He found cucurbita *pepo*, in the middle of a hot fummer's day, lying on the ground exhaufted and flaccid, he thought to recover it by moiftening it with water, but in vain; probably the capacity of the fibre was not then fo great as to receive immediately, without removing the habitual flimuli, light and warmth, fo much oxygen from the water as would have been neceffary to its complete

170

complete recovery, and to collect this, reft during the night was requifite, when the altered temperature and modification of the atmospheric air, and absence of light, are favourable for the reftoration of the tone.

Here Mr. Uflar reminds us of the obfervation, that moft of plants are hurt by moiftening them with cold water in the middle of the day when the temperature is higheft; for although they exhibit for a fhort time a vigorous appearance, yet this is only transfient, and not unfrequently they die prefently thereafter. The cold of the water, and the oxygen communicated by it, eafily induce accumulation, which is fucceeded by irreparable exhauftion.

FIN'IS.
